Preface

Eye injury is a leading cause of visual impairment in the United States with 40,000 to 50,000 new cases of impaired vision reported each year.[1] Many eye injuries occur due to contact with workplace or household products or chemicals. Accidents involving common household products (e.g., oven cleaner and bleach) cause about 125,000 eye injuries each year.[2] These products often cause chemical burns and emergency room visits.[3] Each day about 2,000 U.S. workers have a job-related eye injury that requires medical treatment. Although the majority of these eye injuries result from mechanical sources, chemical burns from industrial chemicals or cleaning products are common.[4]

To prevent eye injuries, regulatory agencies require testing to determine if chemicals and products may cause eye damage. This testing information is used to classify the ocular hazard and determine appropriate labeling to warn consumers and workers of the potential hazard. Appropriate labeling tells users how to avoid exposure that could damage the eye and what emergency procedures should be followed if there is accidental exposure. Nearly all ocular safety testing has been conducted using the Draize rabbit eye test (Draize et al. 1944), although *in vitro* methods can now be used to identify whether substances cause severe irritation or permanent eye damage. The Draize rabbit eye test involves instillation of 0.1 mL of the test substance into the conjunctival sac of one eye. The other eye serves as the untreated control. The eye is examined at least daily for up to 21 days. The presence and severity of any injuries to the cornea, conjunctiva, and the iris (tissues inside the eye) are scored, and the duration that the injuries persist is recorded.

In 2006, the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) evaluated the validation status of the bovine corneal opacity and permeability (BCOP), hen's egg test–chorioallantoic membrane (HET-CAM), isolated chicken eye (ICE), and isolated rabbit eye (IRE) test methods for their ability to identify ocular corrosives and severe irritants. Based on the validation database and performance, ICCVAM recommended that positive results in the BCOP and ICE test methods could be used to identify ocular corrosives and severe irritants without the need for animal testing. These test methods should always be considered before using animals and should be used where determined appropriate. Following their acceptance by U.S. Federal regulatory agencies in 2008, the National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) and ICCVAM developed Organisation for Economic Co-operation and Development (OECD) international test guidelines for the BCOP and ICE test methods. The OECD adopted the guidelines in 2009.[5] As a result, substances that may cause severe irritation or permanent damage to eyes can now be identified using these methods without the use of live animals in the 31 member countries of the OECD.

This test method evaluation report provides ICCVAM's recommendations regarding the BCOP, HET-CAM, ICE, and IRE test methods for identifying nonsevere ocular irritants and substances not labeled as irritants. The report also includes recommendations on the Cytosensor® Microphysiometer (CM) test method, which was not part of the 2006 evaluation. The report summarizes the validation status of each test method and provides the ICCVAM-recommended BCOP, CM, HET-CAM, ICE, and IRE test method protocols.

Paris:Organisation for Economic Co-operation and Development

As part of ICCVAM's ongoing international collaborations, scientists from the European Centre for the Validation of Alternative Methods (ECVAM) and the Japanese Center for the Validation of Alternative Methods (JaCVAM) served as liaisons to the ICCVAM Ocular Toxicity Working Group (OTWG). ICCVAM, NICEATM, and the OTWG prepared (1) draft background review documents (BRDs) describing the validation status of each test method, including reliability and accuracy, and (2) draft test method recommendations for their usefulness and limitations.

ICCVAM released these documents to the public for comment prior to a meeting of an independent international scientific peer review panel (Panel). The Panel met in public session on May 19–21, 2009, and prepared a report summarizing its conclusions and recommendations. The Panel report was provided to the Scientific Advisory Committee on Alternative Toxicological Methods (SACATM) along with the draft BRDs, draft test method recommendations, and all public comments. A detailed timeline of the evaluation is included with this report.

ICCVAM solicited and considered public comments and stakeholder involvement throughout the test method evaluation process. ICCVAM considered the SACATM comments, the conclusions of the Panel, and all public comments before finalizing the ICCVAM test method recommendations for each test method. The recommendations and the BRDs, which are provided as appendices, are incorporated in this ICCVAM test method evaluation report. As required by the ICCVAM Authorization Act, ICCVAM will forward its recommendations to U.S. Federal agencies for consideration. Federal agencies must respond to ICCVAM within 180 days after receiving the ICCVAM test method recommendations. ICCVAM recommendations are available to the public on the NICEATM–ICCVAM website, and agency responses will also be made available on the website as they are received.

We gratefully acknowledge the many individuals who contributed to the preparation, review, and revision of this report. We especially recognize the Panel members for their thoughtful evaluations and generous contributions of time and effort. Special thanks are extended to Dr. A. Wallace Hayes for serving as the Panel Chair and to Dr. Paul Bailey, Dr. Donald Sawyer, Dr. Kirk Tarlo, and Dr. Daniel Wilson for their service as Evaluation Group Chairs. We thank the OTWG for assuring a meaningful and comprehensive review. We especially thank Dr. Jill Merrill (U.S. Food and Drug Administration Center for Drug Evaluation and Research) and Dr. Karen Hamernik (EPA, until April 2009) for serving as Co-Chairs of the OTWG. Integrated Laboratory Systems, Inc., the NICEATM support contractor, provided excellent scientific support, for which we thank Dr. David Allen, Dr. Jonathan Hamm, Nelson Johnson, Dr. Brett Jones, Dr. Elizabeth Lipscomb, and James Truax. Finally, we thank the ECVAM liaisons Drs. João Barroso, Thomas Cole, and Valerie Zuang and the JaCVAM liaison Dr. Hajime Kojima for their participation and contributions.

Executive Director, ICCVAM

Executive Summary

The Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) recently evaluated the validation status of test methods to identify substances that cause reversible eye injuries or do not cause sufficient eye damage to require hazard labeling: the bovine corneal opacity and permeability (BCOP), Cytosensor® Microphysiometer (CM), hen's egg test–chorioallantoic membrane (HET-CAM), isolated chicken eye (ICE), and isolated rabbit eye (IRE) test methods. Nearly all ocular safety testing has been conducted using the *in vivo* Draize rabbit eye test (Draize et al. 1944) to evaluate the potential for substances to cause ocular irritation and other ocular injuries, an acute reaction that may involve corneal cloudiness and ulceration, swelling and redness of the conjunctiva, and/or visible damage to the inside of the eye (iritis). The BCOP, CM, HET-CAM, ICE, and IRE methods are *in vitro* test methods that predict the extent of ocular damage that might occur *in vivo* without requiring the use of live animals. This test method evaluation report provides ICCVAM's recommendations for each *in vitro* test method as an alternative to the Draize rabbit eye test, based on demonstrated validity (usefulness and limitations). This report includes (1) protocols recommended by ICCVAM for future data collection and evaluation for the BCOP, CM, HET-CAM, ICE, and IRE test methods, (2) final background review documents (BRDs) describing the validation status of these test methods, and (3) recommendations for future studies.

Following a nomination by the U.S. Environmental Protection Agency (EPA) requesting an evaluation of several alternative methods and approaches for reducing, replacing, and refining the use of rabbits in the current *in vivo* eye irritation test method, the National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM), ICCVAM, and the ICCVAM Ocular Toxicology Working Group prepared draft BRDs and draft test method recommendations. The drafts were provided to an independent international scientific peer review panel (hereafter "Panel") and to the public for comment. The Panel met in public session on May 19-21, 2009, to discuss its peer review of the ICCVAM draft BRDs and to provide conclusions and recommendations regarding the validation status of the BCOP, CM, HET-CAM, ICE, and IRE test methods. The Panel also reviewed how well the information contained in the draft BRDs supported ICCVAM's draft test method recommendations.

In finalizing this test method evaluation report and the BRDs, which are included here as appendices, ICCVAM considered (1) the conclusions and recommendations of the Panel, (2) comments from ICCVAM's Scientific Advisory Committee on Alternative Toxicological Methods (SACATM), and (3) public comments.

The Bovine Corneal Opacity and Permeability (BCOP) Test Method

ICCVAM Recommendations: BCOP Test Method Usefulness and Limitations
ICCVAM concludes that the accuracy and reliability of the BCOP test method does **not** support its use as a screening test to distinguish substances not labeled as irritants (EPA Category IV, European Union [EU] Not Labeled, Federal Hazardous Substances Act [FHSA] Not Labeled, United Nations Globally Harmonized System of Classification and Labelling of Chemicals [GHS] Not Classified) from all other hazard categories (EPA Category I, II, or III; EU R41 or R36; FHSA Irritant; GHS Category 1, 2A, or 2B) when results are to be used specifically to classify and label substances under the EPA, EU, FHSA, or GHS classification systems. For the BCOP validation database of 211 substances, false positive rates were high, ranging from 53% (24/45) to 70% (63/90), depending on the hazard classification system used. Therefore, all positive results from these tests would require additional testing in a valid test system that can accurately characterize whether such substances require hazard labeling. False negative rates were 0% for the EU (0/54) and GHS (0/97) classification systems, 5% (6/132) for the FHSA classification system, and 6% (8/142) for the EPA classification system.

Among the eight EPA false negatives were three substances (3/8 [38%]) that were classified as EPA eye irritants based on at least one rabbit with corneal injuries and opacity that did not resolve until day 3 of the study. A fourth substance was classified as an EPA eye irritant based on all six rabbits with a conjunctival redness score of 2 (n = 4; *diffuse, crimson color of the conjunctiva, individual blood vessels not easily discernable*) or 3 (n = 2; *diffuse beefy red*). The conjunctival redness scores for two of these animals did not recover to a score of 1 (*some blood vessels definitely hyperemic*) until day 6 of the study. The conjunctival redness scores for the remaining four rabbits recovered to a score of 1 on day 2 of the study. These four EPA false negative substances were also false negatives for the FHSA classification system. Given the significant lesions associated with these false negative substances, the BCOP test method cannot be recommended as a screening test to identify substances not labeled as irritants (i.e., EPA Category IV, FHSA Not Labeled) for the EPA or FHSA classification systems.

Furthermore, although the false negative rate was 0% (0/97) for the GHS classification scheme, the GHS does not classify substances as eye hazards that produce the corneal and conjunctival injuries described above, which are required to be labeled as eye hazards according to the EPA and FHSA classification systems. These findings led NICEATM-ICCVAM to look more closely at the GHS eye hazard classification criteria. NICEATM evaluated results from rabbit eye test studies from two independent databases: (1) 149 studies obtained from a publicly available database (ECETOC 1998) and (2) 144 studies included in the Organization for Economic Cooperation and Development (OECD) Detailed Review Document on Classification Systems for Eye Irritation/Corrosion in OECD Member Countries (OECD 1999). These data, which are included here as an appendix, confirmed that approximately 30% of the substances requiring labeling for eye irritation hazard based on current U.S. hazard classification requirements (EPA and FHSA) are not labeled as eye irritation hazards by the GHS system. This includes at least 70% of currently labeled EPA Category III irritants (those causing eye injuries persisting for 24 hours to 7 days) that would not require hazard labeling using the GHS system. The nature, severity, and duration of these eye injuries suggest the potential to cause human injury. The purpose of ocular toxicity labeling is to communicate potential hazards of chemicals and products to workers and consumers so that appropriate measures can be taken to avoid accidental or inadvertent contact with the eye. In addition, ocular safety labels provide the necessary first aid measures that should be taken in the event of accidental exposures.

The GHS was established based on principles agreed to by participants, which included assuring that "the level of protection offered to workers, consumers, the general public and the environment should not be reduced as a result of harmonizing the classification and labeling systems" (UN 2007). ICCVAM has conducted technical analyses to support the development of appropriate recommendations for GHS options that would continue to provide protection that is at least equivalent to current U.S. eye irritation hazard classification and labeling requirements. ICCVAM recommends that U.S. agencies consider the GHS eye irritation hazard classification criteria and hazard categories and the level of protection they provide compared to current U.S. hazard classification systems.

Federal law requires agencies to determine that new test methods recommended by ICCVAM generate data that are at least equivalent to data generated by current test methods required or recommended by each agency for hazard identification purposes. Until the issues associated with the GHS system as outlined above are further discussed, ICCVAM is deferring final recommendations on the usefulness and limitations of using the BCOP test method as a screening test to identify substances not labeled as irritants according to the GHS classification system.

ICCVAM Recommendations: BCOP Test Method Protocol

For use of the BCOP test method as a screening test to identify substances as ocular corrosives and severe irritants (EPA Category I, EU R41, GHS Category 1), ICCVAM recommends using the

updated ICCVAM BCOP test method protocol included as an appendix to this report. All future studies intended to further characterize the usefulness and limitations of the BCOP test method should be conducted using this protocol.

ICCVAM Recommendations: BCOP Future Studies
ICCVAM recommends additional studies to further characterize and potentially improve the usefulness and applicability of the BCOP test method to distinguish ocular irritants from all hazard categories:

- Additional optimization studies/evaluations should be conducted to improve the correct classification of mild and moderate ocular irritants and substances not labeled as irritants. After optimization, additional studies to further assess the reliability and accuracy of the test method are recommended.
- Histopathological evaluation of the corneal tissue, using standardized procedures, should be included when the BCOP test method is used. Such data will help develop decision criteria and future assessments on the usefulness of this endpoint for classifying and labeling substances, especially those that may otherwise produce borderline or false negative results.
- Users of the BCOP test method should provide all data that are generated from future studies, because they could help to further characterize the usefulness and limitations of the BCOP test method to identify all ocular hazard categories.

ICCVAM Recommendations: BCOP Performance Standards
Based on the available data and associated performance described above, ICCVAM recommends that the development of performance standards for the BCOP test method is not warranted at this time.

Validation Status of the BCOP Test Method
The BCOP test method is an *in vitro* method that provides short-term maintenance of physiological and biochemical function of the bovine cornea. Quantitative changes in opacity and fluorescein permeability are assessed as indicators of potential ocular irritation.

The accuracy of the BCOP test method was compared to hazard categories based on *in vivo* Draize rabbit eye test data according to the EPA, EU, FHSA, or GHS systems using the current BCOP validation database of 211 substances. When the BCOP test method was used to distinguish substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories, accuracy ranged from 64% (76/118) to 83% (161/194), depending on the hazard classification system used. While false positive rates were high (53% [24/45] to 70% [63/90], depending on the hazard classification system used), the false negative rates were low (5% [6/132] for the FHSA system, 6% [8/141] for EPA the system, and 0% [0/54 or 0/97] for the EU and GHS systems, respectively).

Qualitative analyses of interlaboratory reproducibility were conducted to evaluate how well the BCOP hazard classifications agreed among the participating laboratories from the three different interlaboratory validation studies (Balls et al. 1995; Gautheron et al. 1994; and Southee 1998). These evaluations were based on the use of the BCOP test method (1) to identify all ocular hazard categories according to the EPA, EU, or GHS systems, and (2) to distinguish substances not labeled as irritants from all other ocular hazard categories. For both approaches, there was 100% agreement among the multiple laboratories in each study for a majority of the correctly identified ocular irritant hazard categories. Because the performance of the BCOP test method was similar for the EPA and FHSA hazard classification systems, additional reliability analyses were not conducted for the FHSA hazard classification system.

The Cytosensor Microphysiometer (CM) Test Method

ICCVAM Recommendations: CM Test Method Usefulness and Limitations

ICCVAM concludes that the accuracy and reliability of the CM test method support its use as a screening test to identify water-soluble substances (water-soluble surfactants, surfactant-containing formulations, and nonsurfactants) as ocular corrosives and severe irritants (EPA Category I, EU R41, GHS Category 1) in a tiered-testing strategy, as part of a weight-of-evidence approach. False positive rates ranged from 0% (0/17 or 0/18) to 10% (3/29), and false negative rates ranged from 9% (2/23) to 50% (6/12), depending on the classification system used and the type of substance tested. A substance that tests negative with the CM test method would need to be tested in another test method that can identify possible *in vitro* false negative ocular corrosives and severe irritants and distinguish between moderate and mild ocular irritants. Currently, the Draize rabbit eye test is the only test method that can make such a distinction.

ICCVAM further concludes that the accuracy and reliability of the CM test method are sufficient to support its use as a screening test to distinguish water-soluble surfactant chemicals and certain types of surfactant-containing formulations (e.g., cosmetics and personal care product formulations, but not pesticide formulations) as substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled) from all other hazard categories (EPA Category I, II, III; EU R41, R36; FHSA Irritant) when results are to be used specifically to classify and label substances under the EPA, EU, and FHSA classification systems. As noted above, until the issues associated with the GHS classification system are further discussed (see "BCOP Test Method Usefulness and Limitations"), ICCVAM is deferring final recommendations on the usefulness and limitations of using the CM test method as a screening test to identify substances not labeled as irritants according to the GHS classification system.

When the CM test method was used to distinguish substances not listed as irritants from all other hazard categories the validation database of 53 water-soluble surfactants and surfactant-containing formulations, false positive rates were high, ranging from 50% (3/6) to 69% (18/26), depending on the hazard classification system used. However, such positive results would require additional testing in a valid test system that can accurately characterize whether such substances require hazard labeling. Positive results would also need to be additionally tested with methods that can correctly identify moderate and mild ocular irritants. False negative rates ranged from 0% (0/27, 0/28, or 0/40) to 2% (1/42 or 1/47) compared to results from the Draize rabbit eye test. The one false negative substance was EPA Category III or FHSA Irritant based on *in vivo* data. For this substance, six test animals were included in the *in vivo* test. One test animal had no observable effects, three test animals had conjunctival redness (score = 1), and two test animals had corneal opacity (score = 1) that cleared after one day.

Because of the high false negative rates (24% [5/21] to 40% [8/20]for the CM test method when testing water-soluble nonsurfactant substances and formulations, the CM test method is **not** recommended as a screening test to identify substances not labeled as irritants among these types of substances.

Given that the CM test method (INVITTOX Protocol 102) is proposed for use as a screening test to identify ocular corrosives and severe irritants and substances not labeled as irritants, users may want to consider using the CM test method before using another *in vitro* ocular test method for testing these types of substances. However, water-soluble substances that are not identified as ocular corrosives and severe irritants or water-soluble surfactant chemicals and specific types of surfactant-containing formulations that are not identified as substances not labeled as irritants with the CM test method would need to be tested in another test method able to correctly classify substances into each of the four EPA or GHS hazard classification categories. Currently, the only test method accepted for these purposes is the Draize rabbit eye test. Because the CM test method has a high false positive rate for

substances not labeled as irritants (50% [3/6] to 69% [18/26], depending on the hazard classification system used), users may not want to use it if the intended use is to start with identifying substances not labeled as irritants.

ICCVAM Recommendations: CM Test Method Protocol

For use of the CM test method as a screening test to identify water-soluble substances as ocular corrosives and severe irritants (EPA Category I, EU R41, GHS Category 1) or to identify substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled), ICCVAM recommends using the updated ICCVAM CM INVITTOX Protocol 102[6] that is included as an appendix to this report. All future studies intended to further characterize the usefulness and limitations of the CM test method should be conducted using this protocol.

ICCVAM Recommendations: CM Future Studies

ICCVAM recommends that additional studies be conducted to further characterize the usefulness and limitations of the CM test method for use as a screening test to identify ocular corrosives and severe irritants (EPA Category I, GHS Category 1, EU R41) and substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified). This includes additional testing using a broader range of materials to expand the recommended types of substances appropriate for testing.

ICCVAM recommends that a subset of the ICCVAM-recommended reference substances for validation of *in vitro* ocular toxicity test methods for the evaluation of ocular corrosives and severe irritants[7] be tested in the CM test method in order to provide for more direct assessment of the CM test method's utility as a screening test for identifying ocular corrosives and severe irritants. Similarly, a reference set could also be selected from this list for the purposes of assessing the utility of the CM test method as a screening test for identifying substances not labeled as irritants.

Finally, ICCVAM recommends future optimization studies to increase the ability of the CM test method to identify all categories of ocular irritancy hazard classification according to the EPA, EU, or GHS hazard classification systems. This will require more substances in the moderate and mild ocular irritant categories (EPA Category II and III, EU Category R36, or GHS Category 2A and 2B, respectively) be identified and tested.

ICCVAM Recommendations: CM Performance Standards

Based on the available data and associated performance described above, ICCVAM recommends that the development of performance standards for the CM test method is not warranted at this time.

Validation Status of the CM Test Method

The CM test method exposes a population of cells to increasing concentrations of a test substance. The concentration that leads to a 50% decline in the metabolic rate of the cells (the MRD_{50}) is used as an indicator of ocular irritancy potential. An abbreviated version of the European Centre for the Validation of Alternative Methods (ECVAM) CM BRD that does not include confidential business information describes the current validation status of the CM test method, including what is known about its reliability and accuracy, the scope of substances tested, and standardized protocols for the validation study. The following is a synopsis of the information contained within three peer-reviewed publications (Balls et al. 1995; Gettings et al. 1996; Brantom et al. 1997) described in the ECVAM CM BRD and used in the ICCVAM review.

[6] Available at http://ecvam-dbalm.jrc.ec.europa.eu/

[7] http://iccvam.niehs.nih.gov/methods/ocutox/ivocutox/ocu_tmer.htm

The database of 53 water-soluble surfactants tested in the CM test method included 21 surfactant chemicals and 32 surfactant-containing formulations tested across seven different laboratories. Using INVITTOX Protocol 102 to identify ocular corrosives and severe irritants among the water-soluble surfactants and surfactant-containing formulations, the false positive rate ranged from 3% (1/30) to 10% (3/29), depending on the hazard classification system used, compared to *in vivo* results. The three false positives when using the EPA classification system are classified as Category II (n = 2) or III (n = 1) based on *in vivo* data. The one false positive when using the GHS and EU classification systems is classified as Not Classified and Not Labeled, respectively, based on *in vivo* data. The false negative rate ranged from 9% (2/23) to 22% (5/23), depending on the hazard classification system used, compared to *in vivo* results. In each case, these substances were classified as moderate or mild irritants *in vitro* based on the EPA, EU, and GHS classification systems (i.e., EPA Category II or III; EU R36; or GHS Category 2A or 2B).

The nonsurfactant substances database (n = 29) consisted of 27 water-soluble nonsurfactant chemicals, which included a range of chemical classes (e.g., acids, alcohols, alkalis, and ketones), and water-soluble nonsurfactant formulations (n = 2) tested in seven laboratories. Using INVITTOX Protocol 102 to identify ocular corrosives and severe irritants among the nonsurfactant substances, the false positive rate was 0% (0/17 or 0/18) for all hazard classification systems compared to *in vivo* results. The false negative rate ranged from 29% (2/7) to 50% (6/12), depending on the hazard classification system used, compared to *in vivo* results. Two substances were false negatives when using the EPA classification system and were classified *in vitro* as either Category II/III (n = 1) or IV (n = 1). Five substances were false negatives when using the GHS classification system and were classified *in vitro* as either Category 2A/2B (n = 4) or Not Labeled (n = 1). Six substances were false negatives when using the EU classification system and were classified *in vitro* as either R36 (n = 5) or Not Labeled (n = 1).

Using INVITTOX Protocol 102 to identify substances not labeled as irritants among the database of 53 water-soluble surfactants and surfactant-containing formulations, the false negative rate ranged from 0% (0/27 or 0/28, or 0/40) to 2% (1/46 or 1/47), depending on the hazard classification system used, compared to *in vivo* results. The one substance that was a false negative is classified as EPA Category III based on *in vivo* data from a six-rabbit *in vivo* test. One rabbit had no observable effects, three rabbits had conjunctival redness (score = 1), and two rabbits had corneal opacity (score = 1) that cleared after one day. The false positive rate ranged from 50% (3/6) to 69% (18/ 26), depending on the hazard classification system used, compared to *in vivo* results. Three substances were false positives when using the EPA and FHSA classification systems and were classified *in vitro* as Category II/III or Irritant, respectively. Seventeen substances were false positives when using the GHS classification system and were classified *in vitro* as Category 2A/2B (n = 16) or Category 1 (n = 1). Eighteen substances were false positives when using the EU classification system and were classified *in vitro* as R36 (n = 17) or R41 (n = 1).

Using INVITTOX Protocol 102 to identify substances not labeled as irritants among the database of 29 nonsurfactant substances, the false negative rate ranged from 24% (5/21) to 40% (8/20), and the false positive rate ranged from 25% (1/4 or 2/8) to 40% (2/5), depending on the hazard classification system used, compared to *in vivo* results.

Intralaboratory reproducibility was assessed based on calculated coefficients of variation (CVs) for MRD_{50} values for two different studies. Mean CVs ranged from 10% to 24% and tended to be slightly higher for surfactant substances than for nonsurfactant substances.

Interlaboratory reproducibility of the CM test method was also assessed using the data from validation studies by the European Commission/Home Office (EC/HO; Balls et al. 1995) and European Cosmetic, Toiletry and Perfumery Association (COLIPA; Brantom et al. 1997), which included four laboratories and two laboratories, respectively. Mean CVs in the EC/HO study ranged

from 16% to 37% for surfactant substances and up to 51% for nonsurfactant substances. For surfactant materials, all four laboratories using the CM test method had 100% agreement for 55% (6/11) of the test substances; 75% of the laboratories had identical results for 27% (3/11) of the test substances; and 50% of the laboratories had agreement for 18% (2/11) of the test substances. For nonsurfactant substances, agreement among the laboratories was 100% for 48% (11/23) of the test substances, 75% for 22% (5/23) of the test substances, 67% for 4% (1/23) of the test substances, and 50% for 13% (3/23) of the test substances.

For the COLIPA study, substances were divided into surfactant materials, surfactant-based formulations and mixtures, and nonsurfactant substances. Two laboratories had mean between-laboratory CVs ranging from 16% to 23% for surfactant materials, approximately 16% for surfactant-based formulations and mixtures, and 32% to 51% for nonsurfactant substances. For surfactant materials, the laboratories had 100% agreement for 90% (9/10) of the test substances and 0% agreement for 10% (1/10) of the test substances. For surfactant-based formulations and mixtures, the laboratories had 100% agreement for 100% (7/7) of the test substances. For nonsurfactant substances, the laboratories had 100% agreement for 78% (7/9) of the test substances and 0% agreement for 22% (2/9) of the test substances.

The Hen's Egg Test – Chorioallantoic Membrane (HET-CAM) Test Method

ICCVAM Recommendations: HET-CAM Test Method Usefulness and Limitations

ICCVAM concludes that the accuracy and reliability of the HET-CAM test method does **not** support its use as a screening test to distinguish substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled) from all other hazard categories (EPA Category I, II, or III; EU R41 or R36; FHSA Irritant) when results are to be used specifically to classify and label substances under the EPA, EU, or FHSA classification systems.

The available validation database for the HET-CAM test method has remained unchanged since the original ICCVAM evaluation (ICCVAM 2006b). For the HET-CAM validation database of 60 surfactants and oil/water emulsions, false positive rates were 60% (9/15) to 69% (22/32) and false negative rates were 0% (0/26) to 9% (4/45). Among the four false negatives, 100% (4/4) were EPA Category III substances based on conjunctival redness scores of 2 that required at least three days to resolve. For one of the substances, one of the six rabbits tested had a conjunctival redness score of 2 that required 14 days to resolve. Four of the remaining five rabbits in this study had conjunctival redness scores of 2 that resolved within three days; the last rabbit did not have this lesion. However, there were too few substances in the moderate irritant categories to have sufficient confidence in the ability of HET-CAM to distinguish them from the substances not labeled as irritants category (there were only 2 EPA Category II substances).

ICCVAM Recommendations: HET-CAM Test Method Protocol

The updated ICCVAM-recommended HET-CAM test method protocol is included as an appendix to this report. The protocol has been modified from a generic description of the Irritation Score (IS) analysis method to include a more detailed IS(A) analysis method to be used for prospective studies. However, a description of the IS(B) method is included for retrospective analyses, where IS(B) analysis method data could be converted to fixed time points similar to those used for the IS(A) analysis method. All future studies intended to further characterize the usefulness and limitations of the HET-CAM test method should be conducted using this protocol.

ICCVAM Recommendations: HET-CAM Future Studies
ICCVAM recommends additional studies to further characterize and potentially improve the usefulness and applicability of the HET-CAM test method to distinguish ocular irritants from all hazard categories:

- Additional studies should be conducted to further optimize the HET-CAM test method decision criteria that would be used to identify ocular corrosives and severe irritants (EPA Category I, EU R41, GHS Category 1), as well as moderate irritants (EPA Category II, EU R36, GHS Category 2A) and mild irritants (EPA Category III, GHS Category 2B), as defined by the EPA, GHS, or EU classification systems. Such studies could potentially improve the usefulness of the HET-CAM test method for identifying these types of substances.
- The types of substances appropriate for testing should be expanded to include a broader range of chemical and product classes.
- Users of the HET-CAM test method should provide all data that are generated from future studies, because they could help to further characterize the usefulness and limitations of the HET-CAM test method to identify all ocular hazard categories.

ICCVAM Recommendations: HET-CAM Performance Standards
Based on the available data and associated performance described above, ICCVAM recommends that the development of performance standards for the HET-CAM test method is not warranted at this time.

Validation Status of the HET-CAM Test Method
ICCVAM reviewed HET-CAM performance compared to the Draize rabbit eye test for each classification system (EPA, EU, and GHS) using each of the six HET-CAM protocols (IS[A], IS[B], Q-Score, S-Score, IS, and ITC protocols). With the exception of the IS(A) and IS(B) protocols, all protocols classified at least one *in vivo* moderate or severe irritant substance as a substance not labeled as an irritant (EPA Category IV, EU Not Labeled, GHS Not Classified). The IS(B) overpredicted more than 90% (39/42) of the GHS Not Classified substances. Therefore, more extensive analyses of HET-CAM were restricted to the IS(A) protocol.

No new HET-CAM data have been obtained since the ICCVAM evaluation of the HET-CAM test method for identifying ocular corrosives and severe irritants (ICCVAM 2006b). Overall accuracy in distinguishing substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories ranged from 62% (36/58) to 80% (44/55), depending on the hazard classification system used. False positive rates were 60% (9/15) to 69% (22/32) and false negative rates were 0% (0/26) to 9% (4/45). Among the four false negatives, 100% (4/4, all oil/water emulsion cosmetic formulations) were EPA Category III substances based on conjunctival redness scores of 2 that required at least three days to resolve. For one of the substances, one out of the six rabbits tested had a conjunctival redness score of 2 that required 14 days to resolve. Four of the remaining five rabbits in this study had conjunctival redness scores of 2 that resolved within three days; the last rabbit did not have this lesion.

Quantitative and qualitative evaluations of HET-CAM test method reliability have been conducted previously (ICCVAM 2006b). Because the database used for the current evaluation of the HET-CAM test method has not changed, the quantitative evaluation of test method reliability remains unchanged. Additional qualitative analyses of interlaboratory reproducibility were conducted to evaluate how well the HET-CAM hazard classifications agreed among the five laboratories that participated in the interlaboratory validation study (Hagino et al. 1999). These evaluations were based on the use of the HET-CAM test method (1) to identify all ocular hazard categories according to the EPA, EU, or GHS systems, and (2) to distinguish substances not labeled as irritants from all other ocular hazard

categories. For both approaches, there was 100% agreement among the multiple laboratories in each study for a majority of the correctly identified ocular irritant hazard categories. Because the performance of the HET-CAM test method was similar for the EPA and FHSA hazard classification systems, additional reliability analyses were not conducted for the FHSA hazard classification system.

The Isolated Chicken Eye (ICE) Test Method

ICCVAM Recommendations: ICE Test Method Usefulness and Limitations
ICCVAM concludes that the accuracy and reliability of the ICE test method does **not** support its use as a screening test to distinguish substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled) from all other hazard categories (EPA Category I, II, or III; EU R41 or R36; FHSA Irritant) when results are to be used specifically to classify and label substances under the EPA, EU, or FHSA classification systems.

The available validation database for the ICE test method has remained unchanged since the original ICCVAM evaluation (ICCVAM 2006c). For the ICE validation database of 175 substances, false positive rates were 11% (10/93) to 34% (27/79) and false negatives rates were 6% (4/62) to 22% (13/60). Among the false negatives, at least one substance was classified as an ocular corrosive/severe irritant based on Draize rabbit eye test data (n = 1 each for the EPA and GHS systems, and n = 6 for the EU system). Considering the public health impact of misclassifying a corrosive substance as Not Labeled, these false negative results cannot be minimized.

ICCVAM Recommendations: ICE Test Method Protocol
For use of the ICE test method as a screening test to identify substances as ocular corrosives and severe irritants (EPA Category I, GHS Category 1, EU R41), ICCVAM recommends using the updated ICCVAM ICE test method protocol that is included as an appendix to this report. All future studies intended to further characterize the usefulness and limitations of the ICE test method should be conducted using this protocol.

ICCVAM Recommendations: ICE Future Studies
ICCVAM recommends additional studies to further characterize and potentially improve the usefulness and applicability of the ICE test method to distinguish ocular irritants from all hazard categories:

- Additional optimization studies should be conducted to improve the correct classification of mild and moderate ocular irritants and substances not labeled as irritants. After optimization, additional studies to further assess the reliability and accuracy of the test method are recommended.
- Histopathological evaluation of the corneal tissue, using standardized procedures, should be included when the ICE test method is used. Such data will help develop decision criteria and future assessments on the usefulness of this endpoint for classifying and labeling substances, especially those that may otherwise produce borderline or false negative results.
- Users of the ICE test method should provide all data that are generated from future studies, because they could help to further characterize the usefulness and limitations of the ICE test method to identify all ocular hazard categories.

ICCVAM Recommendations: ICE Performance Standards
Based on the available data and associated performance described above, ICCVAM recommends that the development of performance standards for the ICE test method is not warranted at this time.

Validation Status of the ICE Test Method

No new ICE data have been obtained since the ICCVAM evaluation of the ICE test method for identifying ocular corrosives and severe irritants (ICCVAM 2006c). Overall accuracy in distinguishing substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories ranged from 78% (110/141) to 85% (130/153), depending on the hazard classification system used. False positive rates were 11% (10/93) to 34% (27/79) and false negative rates were 6% (4/62) to 22% (13/60). Among these false negatives, at least one substance was classified as an ocular corrosive/severe irritant based on Draize rabbit eye test data (n = 1 each for the EPA and GHS systems, and n = 6 for the EU system). Considering the public health impact of misclassifying a corrosive substance as Not Labeled, these false negative results cannot be minimized.

Quantitative and qualitative evaluations of ICE test method reliability have been conducted previously (ICCVAM 2006c). Because the database used for the current evaluation of the ICE test method has not changed, the quantitative evaluation of test method reliability remains unchanged. Additional qualitative analyses of interlaboratory reproducibility were conducted to evaluate how well the ICE hazard classifications agreed among the four laboratories that participated in the interlaboratory validation study (Balls et al. 1995). These evaluations were based on the use of the ICE test method (1) to identify all ocular hazard categories according to the EPA, EU, or GHS systems, and (2) to distinguish substances not labeled as irritants from all other ocular hazard categories. For both approaches, there was 100% agreement among the multiple laboratories in each study for a majority of the correctly identified ocular irritant hazard categories. Because the performance of the ICE test method was similar for the EPA and FHSA classification systems, additional reliability analyses were not conducted for the FHSA classification system.

The Isolated Rabbit Eye (IRE) Test Method

ICCVAM Recommendations: IRE Test Method Usefulness and Limitations

The available validation database for the IRE test method has remained unchanged since the original ICCVAM evaluation (ICCVAM 2006d). Because of the lack of a standardized protocol and insufficient data using all four recommended IRE endpoints, ICCVAM concludes that additional studies are needed before definitive recommendations on the accuracy and reliability of the IRE test method can be made.

ICCVAM Recommendations: IRE Test Method Protocol

An ICCVAM-recommended test method protocol for the IRE test method that should be used for all future IRE studies is included as an appendix to this report. The recommended protocol remains unchanged from the previous ICCVAM evaluation (ICCVAM 2006e) and includes four endpoints that should be measured: maximal corneal opacity (opacity x area), maximal corneal swelling, fluorescein penetration (intensity x area), and assessment of epithelial integrity (at 0.5, 1, 2, 3, and 4 hours after test substance administration.

ICCVAM Recommendations: IRE Future Studies

ICCVAM recommends additional studies to further characterize and potentially improve the usefulness and applicability of the IRE test method to distinguish ocular irritants from all other hazard categories:

- Additional evaluation studies should be conducted to increase the current IRE database and optimize the IRE test method decision criteria. Once these studies are conducted, ICCVAM recommends that additional validation studies be conducted to further evaluate the relevance and reliability of the IRE test method.
- Histopathological evaluation of the corneal tissue, using standardized procedures, should be included when the IRE test method is used. Such data will help develop decision

criteria and future assessments on the usefulness of this endpoint for classifying and labeling substances, especially those that may otherwise produce borderline or false negative results.

- Users of the IRE test method should provide all data that are generated from future studies, because they could help to further characterize the usefulness and limitations of the IRE test method to identify all ocular hazard categories.

ICCVAM Recommendations: IRE Performance Standards

Based on the available data described above, ICCVAM recommends that the development of performance standards for the IRE test method is not warranted at this time.

Validation Status of the IRE Test Method

The performance section of the IRE BRD (ICCVAM 2006d) uses data from Balls et al. (1995), Gettings et al. (1996), and Guerriero et al. (2004). These references were examined for decision criteria that would help classify moderate and mild irritants. There are insufficient data using all four recommended IRE endpoints (corneal opacity, fluorescein penetration, corneal swelling, and observations of significant effect on corneal epithelium) to assess the accuracy and reliability of the IRE test method when all of these endpoints are evaluated in a single study. Furthermore, among the studies that included each endpoint, decision criteria focused on distinguishing ocular corrosives and severe irritants from all other ocular hazard categories (moderate and mild irritants and substances not labeled as irritants) and did not specify decision criteria for each ocular hazard category. For these reasons, an adequate evaluation of the IRE test method for its ability to distinguish substances not labeled as irritants from all other ocular hazard categories is not feasible at this time.

Because of the lack of quantitative IRE test method data for replicate experiments within an individual laboratory, the intralaboratory repeatability and reproducibility of the IRE test method could not be evaluated. However, multilaboratory qualitative and quantitative IRE test data were available for a collaborative study by the Commission of European Communities (CEC 1991) involving three laboratories and a validation study conducted by Balls et al. (1995) involving four laboratories. In the CEC (1991) study, each substance tested was assigned a EU classification (R41, R36, or nonirritant [EU 2001]) based on Draize rabbit eye test results. However, due to the lack of individual rabbit Draize scores, a reliability assessment for the CEC (1991) study using the GHS (UN 2007) or EPA (EPA 2003) classification criteria was not possible. The Balls et al. (1995) data were used for an evaluation of the interlaboratory reproducibility of the IRE test method according to the GHS (UN 2007), EPA (EPA 2003), and EU (EU 2001) classification systems.

ICCVAM Consideration of Public and SACATM Comments

The ICCVAM evaluation process incorporates a high level of transparency. This process is designed to provide numerous opportunities for stakeholder involvement, including submitting written public comments and providing oral comments at ICCVAM independent peer review panel meetings and SACATM meetings. **Table 7-1** lists the nine different opportunities for public comments that were provided during the ICCVAM evaluation of the validation status of alternative ocular safety testing methods and approaches. A total of 37 public comments were received. Comments received in response to or related to the *Federal Register* notices are also available on the NICEATM-ICCVAM website.[8]

[8] Available at http://ntp-apps.niehs.nih.gov/iccvambp/searchPubCom.cfm

This page intentionally left blank

1.0 Introduction

In October 2003, the U.S. Environmental Protection Agency (EPA) submitted to the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) a nomination requesting evaluation of several activities related to reducing, refining, and replacing the use of rabbits in the current *in vivo* eye irritation test method (announced in *Federal Register* [FR] notice 69 FR 13859, March 24, 2004). In response to this nomination, ICCVAM evaluated the validation status of the bovine corneal opacity and permeability (BCOP), hen's egg test–chorioallantoic membrane (HET-CAM), isolated chicken eye (ICE), and isolated rabbit eye (IRE) test methods. ICCVAM evaluated the test methods' ability to identify ocular corrosives and severe (irreversible) irritants using the EPA, United Nations Globally Harmonized System of Classification and Labelling of Chemicals (GHS), and European Union (EU) classification systems.

ICCVAM considered the BCOP and ICE test methods to have sufficient performance to substantiate their use for regulatory hazard classification for some types of substances. The IRE and HET-CAM test methods lacked sufficient performance and/or sufficient data to substantiate their use for regulatory hazard classification. ICCVAM subsequently recommended that the BCOP and ICE test methods should be used in a tiered-testing strategy as part of a weight-of-evidence approach, where positive substances can be classified as ocular corrosives or severe irritants without the need for animal testing.

In accordance with the ICCVAM Authorization Act of 2000 (Public Law 106-545), these recommendations were made available to the public and provided to U.S. Federal agencies for consideration in the *ICCVAM Test Method Evaluation Report – In Vitro Ocular Toxicity Test Methods for Identifying Severe Irritants and Corrosives* (NIH Publication No. 07-4517, available at http://iccvam.niehs.nih.gov/methods/ocutox/ivocutox/ocu_tmer.htm). The ICCVAM recommendations were accepted by U.S. Federal agencies, and the Organisation for Economic Co-operation and Development (OECD) adopted the BCOP and ICE test methods as OECD Test Guidelines 437 and 438, respectively (OECD 2009a, 2009b). When used in this manner, the BCOP and ICE test methods should reduce the number of animals needed for ocular safety testing and refine animal use by avoiding the pain and distress associated with testing severely irritating and corrosive substances.

Among these final recommendations was a charge to further evaluate the usefulness and limitations of the BCOP, HET-CAM, ICE, and IRE test methods for the identification of nonsevere ocular irritants (i.e., substances that induce reversible ocular damage) and substances not labeled as irritants. In addition, the Cytosensor® Microphysiometer (CM) test method was evaluated as proposed by the European Centre for the Validation of Alternative Methods (ECVAM) as a possible alternative test method for the identification of ocular corrosives and severe irritants and substances not labeled as irritants. For these current evaluations, ICCVAM used the EPA, EU, Federal Hazardous Substances Act (FHSA), and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007). The FHSA classification system, which is based on the testing guidelines and associated criteria included in 16 CFR 1500.42 (CPSC 2003), was not used in the original analyses (i.e., ability of the test methods to identify ocular corrosives and severe irritants) because the FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test (Draize et al. 1944) does not distinguish between ocular corrosives and severe irritants and less severe irritants. For this reason, an evaluation to identify ocular corrosives and severe irritants using the FHSA classification system is not possible.

The ICCVAM Ocular Toxicity Working Group (OTWG) was charged with working with the National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) in reviewing these *in vitro* alternatives. Drs. João Barroso, Thomas Cole, and Valerie Zuang were ECVAM liaisons, and Dr. Hajime Kojima was the Japanese Center for the Validation of Alternative Methods (JaCVAM) liaison to the OTWG.

To facilitate peer review, the OTWG and NICEATM, which administers ICCVAM and provides scientific and operational support for ICCVAM activities, prepared comprehensive draft background review documents (BRDs) that provided information and data from validation studies and the scientific literature for the BCOP, HET-CAM, ICE, and IRE test methods. A redacted BRD (i.e., an abbreviated version that does not include confidential business information) for the CM test method was prepared by ECVAM and submitted to NICEATM–ICCVAM for review.

A June 7, 2007, *Federal Register* notice (72 FR 31582, available at http://iccvam.niehs.nih.gov/SuppDocs/FedDocs/FR/FR_E7_10966.pdf) requested data and information on these test methods. In addition, an April 4, 2008 *Federal Register* notice (73 FR 18535, available at http://iccvam.niehs.nih.gov/SuppDocs/FedDocs/FR/FR-E8-6969.pdf) requested nominations of individuals to serve on an independent international scientific peer review panel (Panel). These requests were also disseminated via the ICCVAM electronic mailing list and through direct requests to over 100 stakeholders. In response to these requests, 12 individuals or organizations nominated members to the Panel; however, no test method data were submitted (see **Section 7.0**).

The BRDs form the basis for the ICCVAM test method recommendations described herein. The ECVAM and JaCVAM liaisons to the OTWG provided input and contributed throughout the evaluation process. A detailed timeline of the evaluation is provided in **Appendix A**. The ICCVAM-recommended test method protocol and the BRD for each test method are provided in **Appendices B through F**.

On March 31, 2009, ICCVAM announced the availability of the ICCVAM draft documents and a public Panel meeting to review the validation status of the test methods (74 FR 14556[1]). The ICCVAM draft BRDs and draft test method recommendations were posted on the NICEATM–ICCVAM website. All of the information provided to the Panel and all public comments received before the Panel meeting were made available on the NICEATM–ICCVAM website.[2]

The Panel met in public session on May 19–21, 2009, to review the ICCVAM draft BRDs for completeness and accuracy. The Panel then evaluated (1) the extent to which the draft BRDs addressed established validation and acceptance criteria and (2) the extent to which the BRDs supported ICCVAM's draft test method recommendations. Interested stakeholders from the public were provided opportunities to comment at the Panel meeting. The Panel considered these comments as well as those submitted prior to the meeting before concluding their deliberations. On July 12, 2009, ICCVAM posted the final report of the Panel's recommendations[3] (**Appendix G**) on the NICEATM–ICCVAM website for public review and comment (announced in 74 FR 33444).

ICCVAM provided SACATM with the draft BRDs, the draft Panel report, and all public comments for discussion at their meeting on June 25–26, 2009, where public stakeholders were given another opportunity to comment.

After SACATM's meeting, ICCVAM and the OTWG considered the SACATM comments, the Panel report, and all public comments (**Appendix H**) before finalizing the ICCVAM test method evaluation report and the BRDs provided in this report. As required by the ICCVAM Authorization Act, ICCVAM will make this test method evaluation report and the accompanying final BRDs available to the public and to U.S. Federal agencies for consideration. The relevant U.S. Federal laws, regulations, guidelines, and recommendations for eye irritation/corrosion testing are summarized in **Appendix I**. Federal agencies must respond to ICCVAM within 180 days after receiving ICCVAM test method recommendations. Agency responses will be made available to the public on the NICEATM–ICCVAM website as they are received.

2.0 The Bovine Corneal Opacity and Permeability Test Method

The BCOP test method is an *in vitro* eye irritation test method using isolated bovine corneas that are byproducts from processing plants. In the BCOP test method, changes in corneal opacity caused by chemical damage are determined by measuring decreases in light transmission through the cornea. Changes in permeability of the cornea resulting from chemical damage are determined by measuring increases in the quantity of sodium fluorescein dye that passes through all corneal cell layers. Both measurements are used to calculate an *in vitro* irritancy score (IVIS), which is used to predict the *in vivo* ocular irritation/corrosion potential of a test substance.

ICCVAM previously evaluated the validation status of the BCOP test method as an *in vitro* alternative to the Draize rabbit eye test (Draize et al. 1944) to identify ocular corrosives and severe irritants (i.e., those that induce irreversible ocular damage; EPA Category I, EU R41, GHS Category 1). ICCVAM determined that the reproducibility and accuracy were sufficient to support its use for this purpose for some types of substances (ICCVAM 2006e). U.S. agencies and international organizations (OECD 2009a) have adopted the BCOP test method for this purpose. In the current evaluation, ICCVAM evaluated the validation status of the BCOP test method as an *in vitro* alternative to the Draize rabbit eye test for identifying nonsevere ocular irritants (i.e., those that induce reversible ocular damage [EPA Category II and III, EU R36, GHS Category 2A and 2B]) and substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) according to the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007).

2.1 ICCVAM Recommendations

2.1.1 ICCVAM Recommendations: Test Method Usefulness and Limitations

Evaluation as a Screening Test to Identify Substances Not Labeled as Irritants

ICCVAM concludes that the accuracy and reliability of the BCOP test method do **not** support its use as a screening test to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other hazard categories (i.e., EPA Category I, II, and III; EU R41 or R36; FHSA Irritant; GHS Category 1, 2A, or 2B) when results are to be used specifically for hazard classification and labeling purposes under the EPA, EU, FHSA, or GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007). For the validation database of 211 substances, false positive rates were high, ranging from 53% (24/45) to 70% (63/90) depending on the hazard classification system used. Accordingly, all positive results from these tests would require additional testing in a valid test system that can accurately characterize whether such substances require hazard labeling.

False negative rates were 0% for the EU (0/54) and GHS (0/97) classification systems, 5% (6/132) for the FHSA classification system, and 6% (8/142) for the EPA classification system. Among the EPA false negatives were three substances (3/8 [38%]) classified as EPA eye irritants based on at least one rabbit with corneal injuries and opacity that did not resolve until day 3 of the study. A fourth substance was classified as an EPA eye irritant based on all six rabbits with a conjunctival redness score of 2 (n = 4: *diffuse, crimson color of the conjunctiva, individual blood vessels not easily discernable*) or 3 (n = 2: *diffuse beefy red*). The conjunctival redness scores for two of these animals did not recover to a score of 1 (*some blood vessels definitely hyperemic*) until day 6 of the study. The conjunctival redness scores for the remaining four rabbits recovered to a score of 1 on day 2 of the study. These four EPA false negative substances were also false negatives for the FHSA classification system. Given the significant lesions associated with these false negative substances, the BCOP test method cannot be recommended as a screening test to identify substances not labeled as irritants (i.e., EPA Category IV, FHSA Not Labeled) for the EPA or FHSA classification systems (EPA 2003; FHSA 2005).

Furthermore, although the false negative rate is 0% (0/97) for the GHS classification system (UN 2007), the GHS does not classify as eye hazards substances that produce the corneal and conjunctival injuries described above. Such substances must be labeled as eye hazards according to the EPA and FHSA classification systems. These findings led NICEATM–ICCVAM to look more closely at the GHS eye hazard classification criteria. NICEATM evaluated results from rabbit eye test studies from two independent databases: (1) 149 studies obtained from a publicly available database (ECETOC 1998) and (2) 144 studies included in the Detailed Review Document (DRD) on Classification Systems for Eye Irritation/Corrosion in OECD Member Countries (OECD 1999). These data (**Appendix J**) confirmed that approximately 30% of the substances that require labeling as eye irritation hazards according to current U.S. hazard classification and labeling requirements (EPA and FHSA) are not labeled as eye irritation hazards by the GHS system. This includes at least 70% of currently labeled EPA Category III irritants (those causing eye injuries persisting for 24 hours to 7 days). The nature, severity, and duration of these eye injuries suggest the potential to cause human injury. The purpose of ocular toxicity labeling is to communicate potential hazards of chemicals and products to workers and consumers so that appropriate measures can be taken to avoid accidental or inadvertent contact with the eye. In addition, ocular safety labels provide the necessary first aid measures that should be taken in the event of accidental exposures.

Among the fundamental principles agreed upon by participants establishing the GHS was the assurance that "the level of protection offered to workers, consumers, the general public and the environment should not be reduced as a result of harmonizing the classification and labeling systems" (UN 2007). ICCVAM has conducted technical analyses to support the development of appropriate recommendations for GHS options that would continue to provide at least equivalent protection as current U.S. ocular hazard classification and labeling requirements. ICCVAM recommends that U.S. agencies consider the GHS ocular hazard classification criteria and categories and the level of protection they provide compared to current U.S. hazard classification systems.

Federal law requires agencies to determine that new test methods recommended by ICCVAM generate data that are at least equivalent to that generated by test methods they currently require or recommend for hazard identification purposes. Given that the BCOP test method does not identify eye irritation hazards when using the EU or GHS hazard classification systems that are currently identified using U.S. hazard identification and classification requirements (EPA and FHSA), ICCVAM cannot recommend using the BCOP test method as a screening test to identify substances not labeled as irritants for the GHS classification system. ICCVAM will revisit recommendations for the BCOP test method based on any updates to the GHS eye hazard classification criteria that may occur as a result of the NICEATM analyses.

Identification of Reversible Eye Irritation Hazard Categories

Based on an evaluation of available data and corresponding performance (accuracy and reliability), ICCVAM concludes that the BCOP test method is **not** recommended to identify moderate and mild ocular irritants as defined by the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).[4]

[4] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between mild and moderate ocular irritants.

Table 2-1 *In Vivo* Ocular Lesions from False Negative Substances in the BCOP Test Method Using the EPA Classification System

Compound	N	*In Vivo* Scores[1]			
		Corneal Opacity: Score (day cleared)	Iris: Score (day cleared)	Conjunctival Redness: Score (day cleared)	Chemosis: Score (day cleared)
Dimethylbiquanide	3	N = 1 1(2) N = 1 1(3)	N = 1 1(2)	N = 2 2(3)	N = 2 2(1)
EDTA	3	N = 1 1(3)	N = 2 1(1)	N = 3 2(2)	N = 1 2(1) N = 1 2(2) N = 1 3(2)
Magnesium carbonate	3	N = 1 1(2) N = 1 1(3)	None	None	None
Polyalkenylsuccinate ester/amine salt	6	N = 2 1(2)	None	N = 1 2(6) N = 3 2(2) N = 1 3(2) N = 1 3(6)	N = 1 2(1) N = 1 2(2)
Compound I	6	N = 1 1(2)	None	None	None
Iminodibenzyl	3	N = 3 1(2)	None	None	None
Methylcyclopentane	6	None	None	N = 1 2(3)	None
Tween 20	4	None	None	N = 2 2(2)	None

Abbreviations: N = number of animals.

[1] The following scores are considered positive: CO or IR ≥1 or CC or CR ≥2. Therefore, CO or IR scores of 0 and CC or CR scores of ≤1 are considered cleared.

Evaluation as a Screening Test to Identify Ocular Corrosives and Severe Irritants

In the original ICCVAM evaluation of the BCOP test method as a screening test to identify substances as ocular corrosives and severe irritants, overall accuracy was 79% (113/143) to 81% (119/147), false positive rates were 19% (20/103) to 21% (22/103), and false negative rates were 16% (7/43) to 25% (10/40) depending on the hazard classification system (i.e., EPA Category I, EU R41, GHS Category 1).

Based on the current updated BCOP validation database, which has increased from 145 to 211 substances, overall accuracy of the BCOP test method as a screening test to identify substances as ocular corrosives and severe irritants is 77% (91/118) to 79% (148/187) depending on the hazard classification system (i.e., EPA Category I, EU R41, GHS Category 1).[5] The false positive rate is 23% (29/124) to 24% (29/122), and false negative rates are 15% (10/65) to 21% (7/33) depending on the hazard classification system used. Based on the similar performance statistics of the current and the original databases, the ICCVAM recommendation for the use of the BCOP test method to identify substances as ocular corrosives and severe irritants remains unchanged:

> There are sufficient data to support the use of the BCOP test method, in appropriate circumstances and with certain limitations, as a screening test to identify substances as ocular corrosives and severe irritants (i.e., EPA Category I, GHS Category 1, EU R41) in a tiered-

[5] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between ocular corrosives/severe irritants and less severe irritants. For this reason, an evaluation of the BCOP test method as a screening test to identify ocular corrosives/severe irritants using the FHSA classification system is not possible.

testing strategy, as part of a weight-of-evidence approach. In a tiered-testing strategy, when a positive result is obtained in an appropriately validated *in vitro* test, a test substance may be classified as an ocular hazard without testing in rabbits. A substance that tests negative in the *in vitro* ocular toxicity test would need to be tested in the *in vivo* ocular test to identify possible *in vitro* false negatives and to identify moderate and mild ocular irritants (ICCVAM 2006e).

Independent Peer Review Panel Conclusions and Recommendations

The Panel concluded that the available data and test method performance support the ICCVAM draft recommendations that the BCOP test method is not recommended to distinguish substances from all hazard categories as defined by the EPA, EU, and GHS classification systems. The Panel agreed with ICCVAM that the BCOP test method continue to be recommended as a screening test for severe irritants. The Panel also concluded that the BCOP test method can be used as a screening test to distinguish substances not labeled as irritants from all other hazard categories when results are to be used for EU or GHS hazard classifications. *It should be noted that this recommendation preceded the NICEATM evaluation of the GHS classification system and, therefore, this information was not taken into consideration.* However, like ICCVAM, the Panel concluded that, because of the significant lesions associated with 50% (4/8) of the EPA Category III substances that tested as false negative, the BCOP test method cannot be recommended as a screening test to identify EPA Category IV substances.

2.1.2 ICCVAM Recommendations: BCOP Test Method Protocol

For use of the BCOP test method as a screening test to identify substances as ocular corrosives and severe irritants (i.e., EPA Category I, EU R41, GHS Category 1), ICCVAM recommends using the updated ICCVAM BCOP test method protocol that is included as an appendix to this report (**Appendix B**). In addition, all future studies intended to further characterize the usefulness and limitations of the BCOP test method should be conducted using this protocol.

Independent Peer Review Panel Conclusions and Recommendations

While the BCOP test method protocol was previously reviewed for use in identifying ocular corrosives and severe irritants, the Panel emphasized the importance of protocol elements. They emphasized that use of this protocol to identify mild/moderate ocular irritants in future studies should include (1) methods for harvest and storage of eyes, (2) timeframe from harvest to use of eyes, (3) consistent animal age, (4) screening for existing corneal lesions prior to use, (5) concurrent positive and negative controls, (6) inclusion of an untreated negative control, and (7) refinement of histopathological methodology.

2.1.3 ICCVAM Recommendations: Future Studies for the BCOP Test Method

To further the use of this test method and to evaluate the use of the BCOP test method as a potential replacement for the Draize rabbit eye test or for the identification of mild and moderate ocular irritants (i.e., EPA Category II, III; EU R36; GHS Category 2A, 2B) and substances not labeled as irritants (i.e., EPA Category IV; EU Not Labeled; FHSA Not Labeled; GHS Not Classified), ICCVAM recommends additional studies be considered and undertaken.

- Additional optimization studies/evaluations should be conducted in an attempt to improve the correct classification of mild and moderate ocular irritants and substances not labeled as irritants. After optimization, additional studies to further assess the reliability and accuracy of the test method are recommended.
- ICCVAM recommends that a histopathological evaluation of the corneal tissue, using standardized procedures, be included when the BCOP test method is conducted. Such data will allow for development of decision criteria and future assessments on the usefulness of

this endpoint for classifying and labeling substances, especially those that may otherwise produce borderline or false negative results.

- ICCVAM encourages users to provide all data that are generated from future studies. They could be used to further characterize the usefulness and limitations of the BCOP test method for the identification of all ocular hazard categories.

Independent Peer Review Panel Conclusions and Recommendations

The Panel concluded that the available data support the ICCVAM draft recommendations. The Panel encouraged continued test method development and refinement of the protocol to achieve more accurate classification of mild and moderate irritants. The Panel also recommended that problematic chemical classes within these hazard categories be identified in order to determine if improved performance could be achieved by restricting the applicability domain.

2.1.4 ICCVAM Recommendations: Performance Standards for the BCOP Test Method

Based on the available data and associated performance described in the final ICCVAM BRD (**Appendix C**), ICCVAM recommends that the development of performance standards for the BCOP test method is not warranted at this time.

2.2 Validation Status of the BCOP Test Method

The following is a synopsis of the information in the final ICCVAM BRD (**Appendix C**), which reviews the available data and information for the BCOP test method. The ICCVAM BRD describes the current validation status of the BCOP test method, including what is known about its reliability and accuracy, the scope of substances tested, and standardized protocols for the validation study.

2.2.1 Test Method Description

The BCOP test method is an *in vitro* eye irritation test method using isolated bovine corneas that are byproducts from processing plants. In the BCOP test method, opacity is determined by the amount of light transmitted through the cornea, and permeability is determined by the amount of sodium fluorescein dye that passes through all corneal cell layers. Both measurements are used to calculate an IVIS, which is used to assign an *in vitro* irritancy classification to predict the *in vivo* ocular irritation potential of a test substance.

2.2.2 Validation Database

An online literature search conducted in support of the evaluation of the validation status of the BCOP test method identified four publications containing BCOP test method results. However, none of these publications included raw data or *in vivo* reference data, or they included data cited from earlier studies that were already included in the validation database. Accordingly, these were not added to the database. The results from the BCOP test method for 66 antimicrobial cleaning products (AMCPs) were obtained from a submission to ICCVAM that describes a non-animal approach for evaluating eye irritation potential and labeling requirements for AMCPs. Therefore, the previous validation database for the BCOP test method (ICCVAM 2006a) was updated to include BCOP data for the 66 AMCPs. The updated BCOP validation database contains 211 substances, representing a wide variety of chemical and product classes, and including 135 commercial products or formulations.

Detailed *in vivo* data were necessary to calculate the appropriate EPA, EU, FHSA, and GHS ocular hazard classifications (EPA 2003; EU 2001; FHSA 2005; UN 2007) (**Appendix C**). These data include cornea, iris, and conjunctiva scores for each animal at 24, 48, and 72 hours and/or assessment of the presence or absence of lesions at 7, 14, and 21 days. Thus, some of the test substances for which there was only limited *in vivo* data could not be used for evaluating test method accuracy and reliability. Additionally, because the FHSA classification system is based on a sequential testing

strategy that uses up to 18 animals, only a small percentage of the substances in the test method databases would be classifiable if the FHSA criteria were strictly applied. Therefore, to maximize the number of substances included in these analyses, two separate "proportionality" criteria were applied for the purpose of assigning an FHSA classification. Based on the minimum number of positive animals needed to identify a substance as an irritant using a single 6-animal test in the FHSA sequential testing strategy, a 67% threshold for positive responding animals was used (i.e., at least 2/3 or 4/6 positive animals) to assign an irritant classification. Alternatively, based on the minimum number of positive animals needed (4/18 [22%]) to identify a substance as an irritant when three 6-animal tests are required in the sequential testing strategy, a 20% threshold for positive responding animals was used to assign an irritant classification.

2.2.3 Test Method Accuracy

Identification of All Ocular Hazard Categories

The ability of the BCOP test method to identify all categories of ocular irritation potential was evaluated for the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).[6] As indicated in **Table 2-2**, overall correct classifications ranged from 49% (91/187) to 55% (102/187), depending on the hazard classification system used when evaluating the entire database. Using alternative decision criteria to identify ocular corrosives and severe irritants (i.e., IVIS ≥ 75 [used in the AMCP submission protocol] instead of IVIS ≥ 55.1 [as per the ICCVAM-recommended BCOP protocol]) did not improve test method performance.

Distinguishing Substances Not Labeled as Irritants from All Other Hazard Categories

The ability of the BCOP test method to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other ocular hazard categories (i.e., EPA Category I, II, III; EU R41, R36; FHSA Irritant; GHS Category 1, 2A, 2B), as defined by the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007) was also evaluated.

As indicated in **Table 2-3**, overall accuracy for the identification of substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories ranged from 64% (76/118) to 83% (148/179, 155/107, or 161/194) depending on the hazard classification system used. While false positive rates were high (53% [24/45 or 25/47] to 70% [63/90]) depending on the hazard classification system used), the false negative rates were low (0% [0/54 or 0/97] to 6% [8/142]) depending on the hazard classification system used. All eight of the false negative substances for the EPA classification system were EPA Category III (i.e., ocular injuries to the cornea and/or iris [inside the eye] and/or conjunctival injuries that persisted more than 24 hours but less than 7 days) based on Draize rabbit eye test data (**Table 2-1**). This included three substances (38% [3/8]) that were classified as EPA eye irritants based on at least one rabbit with corneal lesions and opacity that did not resolve until day 3 of the study. A fourth substance was classified as an EPA eye irritant based on all six rabbits with conjunctival redness scores of 3 (*producing diffuse, crimson color of the conjunctiva, individual blood vessels not easily discernable*). The conjunctival redness scores for two of these animals did not recover to a score of 1 (s*ome blood vessels definitely hyperemic*) until day 6 of the study. The conjunctival redness scores for the remaining four rabbits recovered to a score of 1 on day 2 of the study.

[6] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between ocular corrosives/severe irritants and less severe irritants. For this reason, an evaluation of the BCOP test method to identify all ocular hazard categories using the FHSA classification system is not possible.

Table 2-2 Evaluation of the Performance of the BCOP Test Method in Predicting Ocular Irritant Classes Compared to the *In Vivo* Rabbit Eye Test Method, as Defined by EPA, EU, and GHS Classification Systems[1]

Severe using ≥55.1											
	Overall Correct Classification	**Severe[2]**		**Moderate[3]**			**Mild[4]**			**Not Labeled[5]**

Abbreviations: BCOP = bovine corneal opacity and permeability; EPA = U.S. Environmental Protection Agency; EU = European Union; FHSA = U.S. Federal Hazardous Substances Act; GHS = Globally Harmonized System; N = number of substances included in this analysis; No. = data used to calculate the percentage.

[1] GHS classification system (UN 2007): Not Classified vs. Category 1/2A/2B.
EPA classification system (EPA 2003): Category IV vs. Category I/II/III.
EU classification system (EU 2001): Not Labeled vs. R41/R36.
FHSA classification system (FHSA 2005): Not Labeled vs. Irritant.

2.2.4 Test Method Reliability

Interlaboratory Reproducibility

Quantitative and qualitative evaluations of the BCOP test method reliability have been conducted previously (ICCVAM 2006a). However, additional qualitative analyses of interlaboratory reproducibility were conducted to evaluate the extent of agreement of BCOP hazard classifications among the laboratories participating in the three interlaboratory validation studies (Balls et al. 1995; Gautheron et al. 1994; Southee 1998). As was done for the accuracy evaluation, these qualitative evaluations of reproducibility were based on (1) the use of the BCOP test method for identifying all ocular hazard categories according to the EPA, EU, or GHS systems and (2) the use of the BCOP test method to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, GHS Not Classified) from all other ocular hazard categories (i.e., EPA Category I, II, III; EU R41, R36; GHS Category 1, 2A, 2B). Given that the performance of the BCOP test method was similar for the EPA and FHSA classification systems, additional reliability analyses were not conducted for the FHSA classification system.

Using the first approach (i.e., identifying all ocular hazard categories) among the three interlaboratory studies for the Balls et al. (1995) study, there was 100% agreement among the five laboratories for a majority of the Draize ocular corrosives and severe irritants based on all three classification systems, whether they were correctly identified or underclassified by the BCOP test method (e.g., for the GHS system, there was 100% agreement for 88% [15/17] of the correctly identified Category 1 substances). There was also 100% agreement among the five laboratories for 100% (10/10) of the overpredicted Not Labeled substances and for at least 50% (2/4) of the correctly identified Not Labeled substances.

For the Gautheron et al. (1994) study, there was 100% agreement among the 11 laboratories for a majority of the Draize ocular corrosives and severe irritants based on all three classification systems, whether they were correctly identified or underclassified by the BCOP test method (e.g., for the GHS system, there was 100% agreement for 67% [4/6] of the correctly identified Category 1 substances). There was also 100% agreement among the 11 laboratories for a majority of the overpredicted Not Labeled substances (e.g., for the EU system, there was 100% agreement for 54% [7/13] of the

correctly identified Not Labeled substances) and for a majority of the incorrectly identified Not Labeled substances (e.g., for the EU system, there was 100% agreement for 91% [21/23] of the correctly identified substances).

For the Southee (1998) study, there was 100% agreement among the three laboratories for all of the ocular corrosives and severe irritants based on all three classification systems, whether they were correctly identified or underclassified by the BCOP test method (e.g., for the GHS system, there was 100% agreement for 100% [4/4] of the Draize ocular corrosives and severe irritants). There was also 100% agreement among the two correctly identified Not Labeled substances.

Using the second approach (i.e., distinguishing substances not labeled as irritants from all other ocular hazard categories) for the Balls et al. (1995) study, there was 100% agreement for 92% (55/60) to 93% (56/60) of the substances tested *in vitro*, depending on the classification system used. All five laboratories were in 100% agreement on the classification of 50% (2/4) of Not Labeled substances and 94% (32/34) to 96% (48/50) of all other irritant class substances, depending on the classification system used.

For the Gautheron et al. (1994) study, there was 100% agreement among the eleven laboratories for 65% (34/52) of the substances tested *in vitro*, for all classification systems. There was 100% agreement among the laboratories on the classification of 83% (10/12) to 87% (27/31) of all other irritant class substances, depending on the classification system used.

There was 100% agreement among the three laboratories in the Southee (1998) study for 88% (14/16) of the substances tested *in vitro*, for all classification systems. All three laboratories were in 100% agreement on the classification of 100% (2/2) Not Labeled substances and 90% (9/10) to 92% (11/12) of all other irritant class substances, depending on the classification system used.

As stated above, the final ICCVAM BRD (**Appendix C**) provides a comprehensive summary of the current validation status of the BCOP test method, including what is known about its reliability and accuracy, and the scope of substances tested. Raw data for the BCOP test method will be maintained for future use, so that these performance statistics may be updated as additional information becomes available.

2.2.5 Animal Welfare Considerations

The BCOP test method refines animal use. Because these animals are being humanely processed for nonlaboratory purposes, the testing procedure inflicts no additional pain or distress. Substances that are identified as corrosive or severe irritants *in vitro* are excluded from *in vivo* testing.

The BCOP test method can also reduce animal use because the test method utilizes animal species routinely raised as a food source in large numbers and thus replaces the need for laboratory animals.

3.0 The Cytosensor Microphysiometer Test Method

A number of *in vitro* test systems that have been proposed as alternatives to the Draize rabbit eye test rely on cell death as an endpoint. However, reversible cell changes may provide more appropriate endpoints for the assessment of ocular irritation potential. Good correlations have been reported between results obtained from the CM test method and *in vivo* eye irritancy data. The method is noninvasive, and thus allows the determination of recovery of the cells from the toxic insult. The CM test method measures the rate of extracellular acidification of populations of living cells maintained in flow chambers. After establishing a baseline acidification rate for each set of cells and measuring the new rates subsequent to each sample addition, the concentration of test material (w/v%) required to reduce the acidification rate to 50% is computed by interpolation between the rate data points spanning the 50% response level. This value is termed the MRD_{50} and is the endpoint for the test.

ICCVAM evaluated the validation status of the CM test method, which was not part of the ICCVAM 2006 evaluation, as an *in vitro* alternative to the Draize rabbit eye test for identifying ocular corrosives and severe irritants (i.e., those that induce irreversible ocular damage; EPA Category I, EU R41, GHS Category 1) and substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) according to the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007).

3.1 ICCVAM Recommendations

3.1.1 ICCVAM Recommendations: Test Method Usefulness and Limitations

Evaluation as a Screening Test to Identify Substances Not Labeled as Irritants
ICCVAM concludes that the accuracy and reliability of the CM test method are sufficient to support its use as a screening test to distinguish water-soluble surfactant chemicals and certain types of surfactant-containing formulations (e.g., cosmetics and personal care product formulations, but not pesticide formulations) that are not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled) from all other hazard categories (i.e., EPA Category I, II, III; EU R41, R36; FHSA Irritant) when results are to be used specifically for hazard classification and labeling purposes under the EPA, EU and FHSA classification systems (EPA 2003; EU 2001; FHSA 2005). Until the issues associated with the GHS classification system are further discussed (see "BCOP Test Method Usefulness and Limitations"), ICCVAM is deferring final recommendations on the usefulness and limitations of using the CM test method as a screening test to identify substances not labeled as irritants according to the GHS classification system.

When the CM test method was used to distinguish substances not labeled as irritants among the database of 53 surfactant-containing substances, the false negative rate ranged from 0% (0/27) to 2% (1/47) depending on the hazard classification system used. The one false negative substance based on *in vivo* data was EPA Category III or FHSA Irritant. For this substance, six test animals were included. One test animal had no observable effects, three test animals had conjunctival redness (score = 1), and two test animals had corneal opacity (score = 1) that cleared after one day.

When the CM test method was used to distinguish substances not labeled as irritants among the database of 29 water-soluble nonsurfactant substances and formulations, the false negative rate ranged from 24% (5/21) to 40% (8/20) depending on the hazard classification system used. Because of these high false negative rates, the CM test method is **not** recommended as a screening test to distinguish substances not labeled as irritants among these types of substances.

Evaluation as a Screening Test to Identify Ocular Corrosives and Severe Irritants
ICCVAM recommends that the CM test method can be used as a screening test to identify water-soluble substances (i.e., water-soluble surfactants, surfactant-containing formulations, and nonsurfactants) as ocular corrosives and severe irritants (i.e., EPA Category I, EU R41, GHS

Category 1[7]) in a tiered-testing strategy, as part of a weight-of-evidence approach.[8] A substance that tests negative with the CM test method would need to be tested in another test method that is capable of identifying possible *in vitro* false negative ocular corrosives and severe irritants and to distinguish between moderate and mild ocular irritants. Currently, the Draize rabbit eye test is the only test method capable of making such a distinction.

Given that the CM test method (INVITTOX Protocol Number 102) is proposed for use as a screening test to identify both ocular corrosives and severe irritants and substances not labeled as irritants, users may want to consider using the CM test method prior to another *in vitro* ocular test method for testing these types of substances. However, testing in another test method would be necessary for certain substances not identified with the CM test method: (1) water-soluble substances that are not identified as ocular corrosives and severe irritants or (2) water-soluble surfactant chemicals and specific types of surfactant-containing formulations that are not identified as substances not labeled as irritants. The other test method must be capable of correctly classifying substances into each of the four hazard classification categories for the EPA or GHS classification systems. Currently, the only test method accepted for these purposes is the Draize rabbit eye test. Because of the high false positive rate (50% [3/6] to 69% [18/26] depending on the hazard classification system used) for substances not labeled as irritants, users may not want to use the CM test method if the intention is to identify substances not labeled as irritants first.

Independent Peer Review Panel Conclusions and Recommendations

The Panel concluded that the CM test method is recommended as a screening test to identify water-soluble surfactant substances as ocular corrosives and severe irritants and substances not labeled as irritants in a tiered-testing strategy, as part of a weight-of-evidence approach. However, major concerns are the continued availability of the instrument used to conduct the CM test method, and what new manufacturing processes, including the subsequent required revalidation, might mean to already existing CM test method data.

When using the CM test method to identify water-soluble surfactant substances as substances not labeled as irritants, the false negative rate for the EU, FHSA-67%, and GHS systems was 0% (0/27 or 0/28). For the EPA system it was 2% (1/46). Therefore, the CM test method was recommended for such testing purposes. The Panel recommended that further studies using the CM test method are needed, in particular for EPA Categories III and IV, and that the available data restrict the applicability domain of the CM test method to water-soluble surfactants and surfactant-based formulations (e.g., cosmetics and personal care products).

3.1.2 ICCVAM Recommendations: CM Test Method Protocol

For use of the CM test method as a screening test to identify water-soluble substances as ocular corrosives and severe irritants (i.e., EPA Category I, EU R41, GHS Category 1), or to identify substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified), ICCVAM recommends using the ICCVAM CM test method protocol that is included as an appendix to this report (**Appendix B**). In addition, all future studies intended to further characterize the usefulness and limitations of the CM test method should be conducted using this protocol.

---

[7] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between ocular corrosives/severe irritants and less severe irritants. For this reason, an evaluation of the CM test method as a screening test to identify ocular corrosives/severe irritants using the FHSA classification system is not possible.

[8] The ECVAM Scientific Advisory Committee (ESAC) has also recommended the CM test method for this purpose and for this limited applicability domain (ESAC 2009; **Appendix K**).

Independent Peer Review Panel Conclusions and Recommendations
The Panel concluded that critical aspects of the CM test method had been adequately justified and described and that the protocol was sufficiently detailed. The Panel supported the use of the recommended protocol for future studies to further characterize the usefulness and limitations of the CM test method. However, they expressed concern that the CM test method is unlikely to be widely used because manufacture of the instrument required to conduct the test method has been discontinued.

3.1.3 ICCVAM Recommendations: Future Studies for the CM Test Method

To expand the applicability domain of the CM test method for the identification of ocular corrosives and severe irritants (i.e., EPA Category I, GHS Category 1, EU R41) and substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified), ICCVAM recommends additional studies be considered and undertaken.

- ICCVAM recommends that these substances be selected from the ICCVAM-recommended reference substances for validation of *in vitro* ocular safety test methods for the evaluation of ocular corrosives and severe irritants[9] in order to provide for a more direct assessment of the CM test method's utility as a screening test for identifying ocular corrosives and severe irritants. Similarly, a reference set could also be selected from this list for the purposes of assessing the utility of the CM test method as a screening test for identifying substances not labeled as irritants.
- ICCVAM recommends that future optimization studies be directed towards increasing the performance of the CM test method for identifying all categories of ocular irritancy hazard classification according to the EPA, EU, or GHS hazard classification systems. This will require that an increased number of substances in the moderate and mild ocular irritant categories (i.e., EPA Category II, III; EU R36; GHS Category 2A, 2B) be identified and tested.
- ICCVAM encourages users to provide all data that are generated from future studies, as they could be used to further characterize the usefulness and limitations of the CM test method for the identification of all ocular hazard categories.

Independent Peer Review Panel Conclusions and Recommendations
The Panel concluded that additional studies should be conducted to further characterize the usefulness and limitations of the CM test method for use as a screening test for identifying ocular corrosives and severe irritants or substances not labeled as irritants. Because the CM test method is limited to testing water-soluble surfactants and certain types of surfactant formulations, the Panel recommended that a range of surfactant concentrations should be tested because surfactants form micelles at higher concentrations, which reduce the number of surfactant molecules available to react with the target tissue.

3.1.4 ICCVAM Recommendations: Performance Standards for the CM Test Method

Based on the available data and associated performance described in the redacted ECVAM CM BRD (**Appendix D**), ICCVAM recommends that the development of performance standards for the CM test method is not warranted at this time.

3.2 Validation Status of the Cytosensor Microphysiometer Test Method

The following is a synopsis of the information for three of the peer-reviewed publications (Balls et al. 1995, Gettings et al. 1996, Brantom et al. 1997) referenced in the redacted ECVAM CM BRD (**Appendix D**) and utilized by ICCVAM in its review. The redacted ECVAM CM BRD describes the

[9] http://iccvam.niehs.nih.gov/methods/ocutox/ivocutox/ocu_tmer.htm

current validation status of the CM test method, including what is known about its reliability and accuracy, the scope of substances tested, and standardized protocols for the validation study.

3.2.1 Test Method Description

The CM test method estimates the metabolic rate (i.e., glucose utilization rate) of cells by measuring the rate of excretion of acid byproducts and resulting decrease in pH of the surrounding medium in an enclosed chamber. The rate of change in pH per unit time becomes the metabolic rate of the population. If a test material causes cytotoxicity to this population of cells it is assumed that the metabolic rate will fall. Although the metabolic rate is the physical parameter that is measured with the CM test method, the magnitude of the metabolic rate itself is not directly related to eye irritation potential. Rather, the reduction of the metabolic rate to 50% of its basal rate is the parameter used to measure the impact of the test article on the test system (L929 cells in almost all cases). The CM test method exposes a population of cells to increasing concentrations of the test article (diluted in medium). The exposure follows a 3-step process. The first step is the exposure to the diluted test article, the second is the test article rinse-out, and the third is the measurement of the metabolic activity. This means that the impact of the exposure is measured immediately, and then a subsequent exposure is performed until the highest testable concentration has been used or the population of cells is severely damaged and the metabolic rate has declined to effectively zero. From the concentration response curve, the concentration that leads to a 50% decline in the metabolic rate of the population (the MRD_{50}) is calculated. The MRD_{50} values are used to compare test materials and provide a measure of ocular irritancy potential.

3.2.2 Validation Database

Data on 53 water-soluble surfactant and surfactant-containing formulations were provided in the redacted ECVAM CM BRD (**Appendix D**), where data from the Draize rabbit eye test were also available to assess the accuracy of the CM test method. The database of 53 water-soluble surfactants tested in the CM test method included 21 surfactant chemicals and 32 surfactant-containing formulations tested across seven different laboratories.

The nonsurfactant substances database (n = 29) consisted of 27 water-soluble nonsurfactant chemicals, which included a range of chemical classes (e.g., acids, alcohols, alkalis, and ketones), and two nonsurfactant formulations (n = 2) tested in seven laboratories.

3.2.3 Test Method Accuracy

Distinguishing Substances Not Labeled as Irritants from All Other Hazard Categories
NICEATM evaluated the CM test method's ability to distinguish substances not labeled as irritants (EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other hazard categories (EPA Category I, II, III; EU R41, R36; FHSA Irritant; GHS Category 1, 2A, 2B), as defined by the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007) among the water-soluble surfactants and surfactant-containing formulations.

As indicated in **Table 3-1**, overall accuracy for the identification of substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories for the water-soluble surfactants and surfactant-containing formulations ranged from 66% (35/53) to 93% (43/46) depending on the hazard classification system used. The false negative rate ranged from 0% (0/27, 0/28, or 0/40) to 2% (1/46 or 1/47) depending on the hazard classification system used. The one false negative in both the EPA and the FHSA-20% classification systems was classified as Category III and Irritant, respectively, based on Draize rabbit eye test data. For this substance, six rabbits were included in the *in vivo* test. One rabbit had no observable effects, three rabbits had conjunctival redness (score = 1), and two rabbits had corneal opacity (score = 1) that cleared after one day.

The ability of the CM test method to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other hazard categories (i.e., EPA Category I, II, III; EU R41, R36; FHSA Irritant; GHS Category 1, 2A, 2B), as defined by the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007) among the water-soluble nonsurfactant substances was also evaluated.

As indicated in **Table 3-2**, overall accuracy for the identification of substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories for the water-soluble nonsurfactant substances ranged from 63% (15/24) to 76% (22/29) depending on the hazard classification system used. The false negative rate ranged from 24% (5/21) to 40% (8/20) depending on the hazard classification system used. Eight substances were false negative when using the EPA, GHS, and FHSA classification systems. In the EPA system, they were classified *in vivo* as Category 1 (n = 1), Category II (n = 3) and Category III (n = 4). In the GHS system, they were classified *in vivo* as Category 1 (n = 1) and Category 2A (n = 7). For the FHSA system, they were classified *in vivo* as Irritant.

Table 3-1 Accuracy of the CM Test Method for Distinguishing Substances Not Labeled as Irritants[1] from All Other Irritant Classes for Surfactant-Containing Substances

[1] GHS classification system (UN 2007): Not Classified vs. Category 1/2A/2B.
EPA classification system (EPA 2003): Category IV vs. Category I/II/III.
EU classification system (EU 2001): Not Labeled vs. R41/R36.
FHSA classification system (FHSA 2005): Not Labeled vs. Irritant.

Distinguishing Ocular Corrosives and Severe Irritants from All Other Hazard Categories

The ability of the CM test method to distinguish ocular corrosives and severe irritants (i.e., EPA Category I, EU R41, GHS Category 1) from all other ocular hazard categories (i.e., EPA Category II, III, IV; EU R36, Not Labeled; GHS Category 2A, 2B, Not Classified) as defined by the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007)[10] was evaluated among the water-soluble surfactants and surfactant-containing formulations.

As indicated in **Table 3-3**, overall accuracy for the identification of ocular corrosives and severe irritants (i.e., EPA Category I, EU R41, GHS Category 1) from all other categories for surfactant-containing substances ranged from 85% (44/52) to 94% (50/53) depending on the hazard classification system used. The false positive rates ranged from 3% (1/30) to 10% (3/29) depending on the hazard classification system used. The three false positives when using the EPA classification system are classified as Category II (n = 2) or III (n = 1) based on Draize rabbit eye test data. The one false positive when using the GHS and EU classification systems is Not Classified and Not Labeled, respectively, based on Draize rabbit eye test data.

Table 3-3 Accuracy of the CM Test Method for Distinguishing Corrosives/Severe Irritants[1] from All Other Irritant Classes for Surfactant-Containing Substances

	N	Accuracy		Sensitivity		Specificity		False Positive Rate		False Negative Rate	
		%	No.	%	No.	%	No.	%	No.	%	No.
GHS	53	94	50/53	91	21/23	97	29/30	3	1/30	9	2/23
EPA	52	85	44/52	78	18/23	90	26/29	10	3/29	22	5/23
EU	53	89	47/53	81	21/26	96	26/27	4	1/27	19	5/26

Abbreviations: CM = Cytosensor Microphysiometer; EPA = U.S. Environmental Protection Agency; EU = European Union; GHS = Globally Harmonized System; N = number of substances included in this analysis; No. = data used to calculate the percentage.

[1] GHS classification system (UN 2007): Category 1 vs. Category 2A/2B/NC.
EPA classification system (EPA 2003): Category I vs. Category II/III/IV.
EU classification system (EU 2001): R41 vs. R36/NL.

The ability of the CM test method to distinguish ocular corrosives and severe irritants (i.e., EPA Category I, EU R41, GHS Category 1) among the water-soluble nonsurfactant substances was evaluated for the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).[11] As indicated in **Table 3-4**, overall accuracy ranged from 79% (23/29) to 92% (23/25) depending on the hazard classification system used. The false positive rate was 0% (0/17 or 0/18) for all classification systems used.

[10] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between ocular corrosives/severe irritants and less severe irritants. For this reason, an evaluation of the CM test method as a screening test to identify ocular corrosives/severe irritants using the FHSA classification system is not possible.

[11] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between ocular corrosives/severe irritants and less severe irritants. For this reason, an evaluation of the CM test method as a screening test to identify ocular corrosives/severe irritants using the FHSA classification system is not possible.

Table 3-4 Accuracy of the CM Test Method for Distinguishing Corrosives/Severe Irritants[1] from All Other Irritant Classes for Nonsurfactant Substances

3.2.4 Test Method Reliability

Interlaboratory Reproducibility

For the CM test method, intralaboratory reproducibility was assessed quantitatively based on calculated coefficients of variation (CVs) for MRD_{50} values for two different studies. Mean CVs ranged from 10% to 24% and tended to be slightly higher for surfactant substances than for nonsurfactant substances.

Interlaboratory reproducibility of the CM test method was also assessed using the data from the European Commission/Home Office (EC/HO; Balls et al. 1995) and European Cosmetic, Toiletry and Perfumery Association (COLIPA; Brantom et al. 1997) validation studies, which included four laboratories and two laboratories, respectively. Mean CVs in the EC/HO study ranged from 16% to 37% for surfactant substances and up to 51% for nonsurfactant substances. For surfactant materials, all four laboratories using the CM test method had 100% agreement for 55% (6/11) of the test substances; 75% of the laboratories had identical results for 27% (3/11) of the test substances; and 50% of the laboratories had agreement for 18% (2/11) of the test substances. For nonsurfactant substances, agreement among the laboratories was 100% for 48% (11/23) of the test substances, 75% for 22% (5/23) of the test substances, 67% for 4% (1/23) of the test substances, and 50% for 13% (3/23) of the test substances.

For the COLIPA study, substances were divided into surfactant materials, surfactant-based formulations and mixtures, and nonsurfactant substances. Two laboratories had mean between-laboratory CVs ranging from 16% to 23% for surfactant materials, approximately 16% for surfactant-based formulations and mixtures, and 32% to 51% for nonsurfactant substances. For surfactant materials, the laboratories had 100% agreement for 90% (9/10) of the test substances and 0% agreement for 10% (1/10) of them. The laboratories had 100% agreement for 100% (7/7) surfactant-based formulations and mixtures. For nonsurfactant substances, the laboratories had 100% agreement for 78% (7/9) of the test substances and 0% agreement for 22% (2/9) of them.

3.2.5 Animal Welfare Considerations

Except for the mice originally used to develop the L929 cell line, no animals are used for the CM test method.

4.0 The Hen's Egg Test–Chorioallantoic Membrane Test Method

The HET-CAM test method uses the chorioallantoic membrane, which is a vascular fetal membrane composed of the fused chorion and allantois. The acute effects induced by a test substance on the small blood vessels and proteins of this soft tissue membrane are used as an indicator of effects induced by the same test substance in the eye of a treated rabbit.

ICCVAM previously evaluated the validation status of the HET-CAM test method as an *in vitro* alternative to the Draize rabbit eye test to identify ocular corrosives and severe irritants (i.e., those that induce irreversible ocular damage; EPA Category I, EU R41, GHS Category 1) and determined that the reproducibility and accuracy was **not** sufficient to support its use for this purpose (ICCVAM 2006e). In the current evaluation, ICCVAM evaluated the validation status of the HET-CAM test as an *in vitro* alternative to the Draize rabbit eye test for identifying nonsevere ocular irritants (i.e., those that induce reversible ocular damage; EPA Category II and III, EU R36, GHS Category 2A and 2B) and substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) according to the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007).

4.1 ICCVAM Recommendations

4.1.1 ICCVAM Recommendations: Test Method Usefulness and Limitations

Evaluation as a Screening Test to Identify Substances Not Labeled as Irritants
Based on the current evaluation, ICCVAM concludes that the scientific validity of the HET-CAM test method has been adequately evaluated and that the HET-CAM test method is **not** recommended as a screening test to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other hazard categories (i.e., EPA Category I, II, III; EU R41, R36; FHSA Irritant; GHS Category 1, 2A, 2B) when results are to be used specifically for hazard classification and labeling purposes under the EPA, EU, FHSA, or GHS hazard classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007). There are too few surfactants or oil/water emulsions in the moderate irritant categories to allow sufficient confidence in the ability of the HET-CAM test method to distinguish them from the substances not labeled as irritants (i.e., there were no GHS Category 2A substances and only two EPA Category II or EU R36 substances).

Identification of Reversible Eye Irritation Hazard Categories
ICCVAM further concludes that, based on an evaluation of available data and corresponding performance (accuracy and reliability), the HET-CAM test method is **not** recommended to identify moderate and mild ocular irritants as defined by the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).[12]

Evaluation as a Screening Test to Identify Ocular Corrosives and Severe Irritants
The available validation database for the HET-CAM test method has remained unchanged since the original ICCVAM evaluation (ICCVAM 2006b). Therefore, the original ICCVAM recommendation for the use of the HET-CAM test method to identify substances as ocular corrosives and severe irritants remains unchanged:

> The use of the HET-CAM test method for screening and identifying ocular corrosives and severe irritants (i.e., EPA Category I, GHS Category 1, EU R41) in a tiered-testing strategy, as part of a weight-of-evidence approach, is **not** recommended (ICCVAM 2006e).

[12] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between mild and moderate ocular irritants.

Independent Peer Review Panel Conclusions and Recommendations
The Panel concluded that the HET-CAM test method cannot identify substances from all hazard categories. The Panel also concluded (with one minority opinion) that the HET-CAM test method using the IS(A) analysis method cannot be used as a screening test to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, GHS Not Classified) from all other hazard categories (i.e., EPA Category I, II, III; EU R41, R36; GHS Category 1, 2A, 2B) when results are to be used for EPA, EU or GHS hazard classifications. The Panel reached this conclusion because there were too few surfactants or oil/water emulsions in the mild to moderate irritant categories to have sufficient confidence in the ability of the test to distinguish them from substances not labeled as irritants.

4.1.2 ICCVAM Recommendations: HET-CAM Test Method Protocol

The updated ICCVAM-recommended HET-CAM test method protocol is included as an appendix to this report (**Appendix B**). The protocol has been modified from a generic description of the IS analysis method to include a more detailed IS(A) analysis method to be used for prospective studies. However, a description of the IS(B) method is included for retrospective analyses, where IS(B) analysis method data could be converted to fixed time points similar to those used for the IS(A) analysis method. All future studies intended to further characterize the usefulness and limitations of the HET-CAM test method should be conducted using this protocol.

Independent Peer Review Panel Conclusions and Recommendations
The Panel concluded that the protocol is sufficiently detailed that it could be conducted reproducibly in other laboratories. However, they emphasized that the protocol should reflect any restrictions of the current applicability domain and it should also reflect details specific to the testing of certain types of substances. In addition, they noted that the protocol reflects the IS(A) analysis method, which was the subject of the ICCVAM draft recommendation, but additional data derived using the IS(B) analysis method could be collected and extrapolated to the IS(A) analysis method.

4.1.3 ICCVAM Recommendations: Future Studies for the HET-CAM Test Method

ICCVAM recommends that additional studies be conducted to further optimize the HET-CAM test method decision criteria that would be used to identify ocular corrosives and severe irritants (EPA Category I, EU R41, GHS Category 1), moderate and mild irritants (i.e., EPA Category II, III; EU R36; GHS Category 2A, 2B), and substances not labeled as irritants (i.e., EPA Category IV; EU Not Labeled; FHSA Not Labeled; GHS Not Classified) as defined by the EPA, EU, FHSA, and GHS classification systems. Such studies could potentially improve the usefulness of the HET-CAM test method for identifying these types of substances.

Additionally, in order to further optimize the protocol and more adequately characterize the usefulness of the HET-CAM test method for identifying substances not labeled as irritants:

- ICCVAM recommends that the applicability domain be expanded to include a broader range of chemical and product classes.
- ICCVAM encourages users to provide all data that are generated from future studies because they could be used to further characterize the usefulness and limitations of the HET-CAM test method for the identification of all ocular hazard categories.

Independent Peer Review Panel Conclusions and Recommendations
In order to further optimize the protocol and more adequately characterize the usefulness of the HET-CAM test method for identifying substances not labeled as irritants, the Panel recommended that additional data be collected on mild and moderate irritants and that the applicability domain be expanded to include a broader range of chemical and product classes.

They also noted that most of the single ingredients tested in the HET-CAM performed poorly, whereas formulations performed better. Hence, the effect of increasing the concentration of single ingredients on accuracy and sensitivity should be assessed in the HET-CAM to determine if there are test substance concentration limits for specific chemical classes.

The Panel did not support additional studies for using the HET-CAM test method to identify all categories of ocular irritants, given that it has been extensively evaluated and proven incapable for this task. However, as noted above, ICCVAM considers such studies valuable because they could improve the usefulness of the HET-CAM test method for identifying these types of substances. Furthermore, it is essential that the full range of ocular irritancy potential be tested in order to establish whether false negatives in the HET-CAM test method present a significant public health risk (e.g., EPA Category I substances predicted as Category IV in the HET-CAM test method).

4.1.4 ICCVAM Recommendations: Performance Standards for the HET-CAM Test Method

Based on the available data and associated performance described in the final ICCVAM BRD (**Appendix E**), ICCVAM recommends that the development of performance standards for the HET-CAM test method is not warranted at this time.

4.2 Validation Status of the HET-CAM Test Method

The following is a synopsis of the information in the final ICCVAM BRD (**Appendix E**), which reviews the available data and information for the HET-CAM test method. The ICCVAM BRD describes the current validation status of the HET-CAM test method, including what is known about its reliability and accuracy, the scope of the substances tested, and standardized protocols for the validation study.

4.2.1 Test Method Description

The HET-CAM protocol, first described by Luepke (1985), uses a vascular fetal membrane, the chorioallantoic membrane (CAM), which is composed of the fused chorion and allantois. The CAM has been proposed as a model for a living membrane (such as the conjunctiva) because it comprises a functional vasculature. Additionally, evaluation of coagulation (i.e., protein denaturation) may reflect corneal damage that may be produced by the test substance. The acute effects induced by a test substance on the small blood vessels and proteins of this soft tissue membrane are proposed to be similar to effects induced by the same test substance in the eye of a treated rabbit.

4.2.2 Validation Database

No new HET-CAM data were obtained since the ICCVAM evaluation of the HET-CAM test method for identifying ocular corrosives and severe irritants (ICCVAM 2006b). Therefore, the same database was used in the current evaluation. The database is composed of 260 substances representing a wide variety of chemical and product classes. It includes more than 50 commercial products or formulations. However, of the 260 substances, 167 could not be classified within a product class.

Analyses of each of the multiple HET-CAM protocols indicate that the IS(A) analysis method achieved the best performance when evaluating substances not labeled as irritants. The available IS(A) database includes a total of 63 test substances, 60 of which had sufficient *in vivo* data to be assigned an ocular irritancy hazard classification. Among these 60 substances are 43 cosmetic and personal care product formulations (including 25 surfactant-based formulations and 18 oil/water emulsions), and 17 individual substances (including seven alcohols; no other classes were represented by more than three substances).

Detailed *in vivo* data were necessary to calculate the appropriate EPA, EU, FHSA, and GHS ocular hazard classifications (EPA 2003; EU 2001; FHSA 2005; UN 2007) (**Appendix E**). These data

consist of cornea, iris and conjunctiva scores for each animal at 24, 48, and 72 hours and/or assessment of the presence or absence of lesions at 7, 14, and 21 days. Thus, some of the test substances for which there was only limited *in vivo* data could not be used to evaluate test method accuracy and reliability. In order to maximize the number of substances included in these analyses, "proportionality" criteria (i.e., FHSA-20% and FHSA-67%) were applied for the purpose of assigning an FHSA classification for test results that would require additional testing according to the FHSA sequential testing strategy (see **Section 2.2.2**).

4.2.3 Test Method Accuracy

Identification of All Ocular Hazard Categories

The ability of the HET-CAM test method to identify all categories of ocular irritation potential was evaluated for the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).[13] As indicated in **Table 4-1**, overall correct classifications ranged from 38% (23/60) to 41% (24/59) depending on the classification system used when evaluating the entire database.

It is apparent from **Table 4-1** that the limited number of substances (n = 0–2) in the moderate irritant category (i.e., EPA Category II, EU R36, and GHS Category 2A) prevents an adequate evaluation of HET-CAM performance for this category. Similarly, while there are 18 substances classified as EPA Category III, there are only five substances classified as GHS Category 2B (the EU system does not distinguish mild irritants).

Distinguishing Substances Not Labeled as Irritants from All Other Hazard Categories

The ability of the HET-CAM test method to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other ocular hazard categories (i.e., EPA Category I, II, III; EU R41, R36; FHSA Irritant; GHS Category 1, 2A, 2B) as defined by the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007) was also evaluated.

As indicated in **Table 4-2**, overall accuracy for the identification of substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories ranged from 62% (36/58) to 80% (44/55) depending on the hazard classification system used. False positive and false negative rates ranged from 60% (9/15) to 69% (22/32) and 0% (0/26 or 0/36) to 9% (4/45 or 4/47), respectively. Among the four false negatives for the EPA and FHSA-20% systems, 100% (4/4, all oil/water emulsion cosmetic formulations) were EPA Category III substances based on a conjunctival redness score of 2 that required at least 3 days to resolve. For one of these substances, one of the six rabbits tested had a conjunctival redness score of 2 that required 14 days to resolve. Four of the remaining five rabbits in this study had conjunctival redness scores of 2 that resolved within three days. The fifth rabbit did not have this lesion.

[13] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between ocular corrosives/severe irritants and less severe irritants. For this reason, an evaluation of the HET-CAM test method to identify all ocular hazard categories using the FHSA classification system is not possible.

Table 4-1 Evaluation of the Performance of the HET-CAM Test Method in Predicting Ocular Irritant Classes Compared to the *In Vivo* Rabbit Eye Test Method, as Defined by the EPA, EU, and GHS Classification Systems[1]

	Overall Correct Classification	Severe[2]		Moderate[3]			Mild[4]			Not Labeled[5]	
		Actual	Under	Over	Actual	Under	Over	Actual	Under	Over	Actual
EPA	38% (23/60)	48% (12/25)	52% (13/25)	50% (1/2)	50% (1/2)	0% (0/2)	56% (10/18)	22% (4/18)	22% (4/18)	60% (9/15)	40% (6/15)
GHS	41% (24/59)	50% (13/26)	50% (13/26)	0% (0/0)	0% (0/0)	0% (0/0)	80% (4/5)	20% (1/5)	0% (0/5)	64% (18/28)	36% (10/28)
EU	40% (23/58)	50% (12/24)	50% (12/24)	50% (1/2)	50% (1/2)	0% (0/2)	NA	NA	NA	69% (22/32)	31% (10/32)

Abbreviations: EPA = U.S. Environmental Protection Agency; EU = European Union; GHS = Globally Harmonized System; HET-CAM = hen's egg test–chorioallantoic membrane; NA = not applicable.

[1] EPA classification system (EPA 2003); EU classification system (EU 2001); GHS classification system (UN 2007).

[2] Severe = GHS Category 1; EPA Category I; EU R41.

[3] Moderate = GHS Category 2A; EPA Category II; EU R36.

[4] Mild = GHS Category 2B; EPA Category III.

[5] Not Labeled = GHS Not Classified; EPA Category IV; EU Not Labeled.

Table 4-2 Accuracy of the HET-CAM Test Method for Distinguishing Substances Not Labeled as Irritants[1] from All Other Irritant Classes

	N	Accuracy		Sensitivity		Specificity		False Positive Rate		False Negative Rate	
		%	No.	%	No.	%	No.	%	No.	%	No.
EPA	60	78	47/60	91	41/45	40	6/15	60	9/15	9	4/45
GHS	59	69	41/59	100	31/31	36	10/28	64	18/28	0	0/31
EU	58	62	36/58	100	26/26	31	10/32	69	22/32	0	0/26
FHSA-20%	63	78	49/63	91	43/47	38	6/16	63	10/16	9	4/47
FHSA-67%	55	80	44/55	97	38/39	38	6/16	63	10/16	3	1/39

Abbreviations: EPA = U.S. Environmental Protection Agency; EU = European Union; FHSA = U.S. Federal Hazardous Substances Act; GHS = Globally Harmonized System; HET-CAM = HET-CAM = hen's egg test–chorioallantoic membrane; N = number of substances included in this analysis; No. = data used to calculate the percentage.

[1] GHS classification system (UN 2007): Not Classified vs. Category 1/2A/2B.
EPA classification system (EPA 2003): Category IV vs. Category I/II/III.
EU classification system (EU 2001): Not Labeled vs. R41/R36.
FHSA classification system (FHSA 2005): Not Labeled vs. Irritant.

4.2.4 Test Method Reliability

Interlaboratory Reproducibility

Quantitative and qualitative evaluations of HET-CAM test method reliability have been conducted previously (ICCVAM 2006b). Because the database used for the current evaluation of the HET-CAM test method has not changed, the quantitative evaluation of test method reliability remains unchanged. However, additional qualitative analyses of interlaboratory reproducibility were conducted to evaluate the extent of agreement of HET-CAM hazard classifications among the five laboratories participating in the interlaboratory validation study (Hagino et al. 1999). As was done for the accuracy evaluation, these qualitative evaluations of reproducibility were based on (1) the use of the HET-CAM test method for identifying all ocular hazard categories according to the EPA, EU, and GHS systems, and (2) the use of the HET-CAM test method to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, GHS Not Classified) from all other irritant categories (i.e., EPA Category I, II, III; EU R41, R36; GHS Category 1, 2A, 2B). Given that the performance of the HET-CAM test method was similar for the EPA and FHSA classification systems, additional reliability analyses were not conducted for the FHSA classification system.

Using the first approach (i.e., identifying all ocular hazard categories), there was 100% agreement among the five laboratories for a majority of the Draize ocular corrosives and severe irritants correctly classified by the HET-CAM test method based on all three classification systems. (There was 100% agreement for 63% [5/8] of the correctly identified EPA Category I substances and 100% agreement for 71% [5/7] of the correctly identified GHS Category 1 or EU R41 substances.) There was 100% agreement among the five laboratories for the one moderate irritant in the database (EPA Category II or EU R36; no GHS Category 2A substances were included), which was overpredicted. There was 100% agreement for the mild ocular irritants (i.e., EPA Category III, GHS Category 2B; the EU does not have a mild irritant category), which were uniformly overpredicted. For the Hagino et al. (1999) database, all of the substances not classified as irritants based on Draize results (i.e., EPA Category IV, EU Not Labeled, GHS Not Classified) were overclassified by the HET-CAM test method. There was 100% agreement among the five laboratories for 86% (6/7) or 75% (3/4) of these substances for the EU and GHS classification systems, respectively. By comparison, for the two EPA Category IV substances tested, there was either 100% or 80% agreement among the five laboratories.

Using the second approach (i.e., identifying substances not labeled as irritants), there was 100% agreement among the five laboratories for 82% (14/17), 76% (13/17), and 94% (16/17) for the 17 substances included in the Hagino et al. (1999) database for the EPA, EU, and GHS classification systems, respectively.

There was 100% agreement among the five laboratories for 100% (13/13) of the substances correctly identified as irritants according to the EPA classification system (i.e., Category I, II, or III). While neither of the EPA Category IV substances was correctly identified by the HET-CAM test method, there was 60% agreement among the five laboratories for 100% (2/2) of the EPA Category IV substances that were overpredicted by the HET-CAM test method.

There was 100% agreement among the five laboratories for 63% (5/8) of the substances correctly identified as an irritant according to the EU classification system (i.e., R36 or R41). There was at least 60% agreement among the five laboratories for the remaining three substances correctly classified as an irritant. While none of the EU Not Labeled substances were correctly identified by the HET-CAM test method, there was 100% agreement among the five laboratories for 86% (6/7) of these substances that were overpredicted by the HET-CAM test method.

There was 100% agreement among the five laboratories for 100% (11/11) of the substances correctly identified as irritants according to the GHS classification system (i.e., Category 1, 2A, or 2B). While none of the GHS Not Classified substances was correctly identified by the HET-CAM test method, there was 100% agreement among the five laboratories for 75% (3/4) of these substances that were overpredicted by the HET-CAM test method.

As stated above, this review provides a comprehensive summary of the current validation status of the HET-CAM test method, including what is known about its reliability and accuracy, and the scope of the substances tested. Raw data for the HET-CAM test method will be maintained for future use, so that these performance statistics may be updated as additional information becomes available.

4.2.5 Animal Welfare Considerations

The HET-CAM test method has the potential to reduce and refine animal use in eye irritation testing. It would refine animal use by the *in vitro* identification of ocular corrosives/severe irritants, nonsevere irritants, or substances not labeled as irritants in a tiered-testing strategy.

5.0 The Isolated Chicken Eye Test Method

The ICE test method is an *in vitro* eye irritation test method using chicken eyes that are byproducts from processing plants. In the ICE test method, damage by the test substance is assessed by determining corneal swelling, opacity, and fluorescein retention. These endpoints are used collectively as an indicator of effects induced by the test substance in the eye of a treated rabbit.

ICCVAM previously evaluated the validation status of the ICE test method as an *in vitro* alternative to the Draize rabbit eye test to identify ocular corrosives/severe irritants (i.e., those that induce irreversible ocular damage; EPA Category I, EU R41, GHS Category 1) and determined that the reproducibility and accuracy was sufficient to support its use for this purpose for some types of substances (ICCVAM 2006e). U.S. agencies and international organizations (OECD 2009b) have adopted the ICE test method for this purpose. Following this initial evaluation, ICCVAM evaluated the validation status of the ICE test method as an *in vitro* alternative to the Draize rabbit eye test for identifying nonsevere ocular irritants (i.e., those that induce reversible ocular damage [EPA Category II and III, EU R36, GHS Category 2A and 2B]) and substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) according to the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007).

5.1 ICCVAM Recommendations

5.1.1 ICCVAM Recommendations: Test Method Usefulness and Limitations

Evaluation as a Screening Test to Identify Substances Not Labeled as Irritants
ICCVAM concludes that the ICE test method is **not** recommended as a screening test to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other hazard categories (i.e., EPA Category I, II, III; EU R41, R36; FHSA Irritant; GHS Category 1, 2A, 2B) when results are to be used specifically for hazard classification and labeling purposes under the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007).

Identification of Reversible Eye Irritation Hazard Categories
Based on an evaluation of available data and test method performance (accuracy and reliability), ICCVAM concludes that the ICE test method is **not** recommended to identify moderate and mild ocular irritants as defined by the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).[14]

Evaluation as a Screening Test to Identify Ocular Corrosives and Severe Irritants
The available validation database for the ICE test method has not changed since the original ICCVAM evaluation (ICCVAM 2006c). Therefore, the original ICCVAM recommendation for the use of the ICE test method to identify substances as ocular corrosives and severe irritants remains unchanged:

> There are sufficient data to support the use of the ICE test method, in appropriate circumstances and with certain limitations, as a screening test to identify substances as ocular corrosives and severe irritants (i.e., EPA Category I, UN GHS Category 1, EU R41) in a tiered-testing strategy, as part of a weight-of-evidence approach. In a tiered-testing strategy, when a positive result is obtained in an appropriately validated *in vitro* test, a test substance may be classified as an ocular hazard without testing in rabbits. A substance that tests negative in the *in vitro* ocular toxicity test would need to be tested in the *in vivo* ocular test to identify possible *in vitro* false negatives and to identify moderate and mild ocular irritants (ICCVAM 2006e).

[14] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between mild and moderate ocular irritants.

Independent Peer Review Panel Conclusions and Recommendations
The Panel concluded that the available data and test method performance (accuracy and reliability) supported the ICCVAM draft recommendation that the ICE test method is not recommended to identify substances from all hazard categories as defined by the EPA, EU, and GHS classification systems. The Panel further concluded that the ICE test method is not recommended as a screening test to distinguish substances as not labeled as irritants from all other hazard categories as defined by the EPA, EU, and GHS classification systems.

5.1.2 ICCVAM Recommendations: ICE Test Method Protocol

For use of the ICE test method as a screening test to identify substances as ocular corrosives and severe irritants (i.e., EPA Category I, EU R41, GHS Category 1), ICCVAM recommends using the updated ICCVAM ICE test method protocol that is included as an appendix to this report (**Appendix B**). In addition, all future studies intended to further characterize the usefulness and limitations of the ICE test method should be conducted using this protocol.

Independent Peer Review Panel Conclusions and Recommendations
The Panel concluded that the protocol is sufficiently detailed but noted that the protocol could be improved by adding objective endpoints for corneal opacity and fluorescein staining.

5.1.3 ICCVAM Recommendations: Future Studies for the ICE Test Method

To further the use of this test method and to evaluate its use as a potential replacement for the Draize rabbit eye test or for the identification of mild and moderate ocular irritants (i.e., EPA Category II, III; EU R36; GHS Category 2A, 2B) and substances not labeled as irritants (i.e., EPA Category IV; EU Not Labeled; FHSA Not Labeled; GHS Not Classified), ICCVAM recommends additional studies be considered and undertaken.

- Additional optimization studies/evaluations should be conducted in an attempt to improve the correct classification of mild and moderate ocular irritants and substances not labeled as irritants. After optimization, additional studies to further assess the reliability and accuracy of the test method are recommended.
- ICCVAM recommends that a histopathological evaluation of the corneal tissue, using standardized procedures, be included when the ICE test method is conducted. Such data will allow for development of decision criteria and future assessments on the usefulness of this endpoint for classifying and labeling substances, especially those that may otherwise produce borderline or false negative results.
- ICCVAM encourages users to provide all data that are generated from future studies, as they could be used to further characterize the usefulness and limitations of the ICE test method for the identification of all ocular hazard categories.

Independent Peer Review Panel Conclusions and Recommendations
The Panel concluded that additional optimization studies should be required to validate the test method for the identification of all ocular irritation hazard categories. The Panel also noted that the use of histopathology to evaluate corneal tissue might improve test method accuracy.

5.1.4 ICCVAM Recommendations: Performance Standards for the ICE Test Method

Based on the available data and associated performance described in the final ICCVAM BRD (**Appendix F**), ICCVAM recommends that the development of performance standards for the ICE test method is not warranted at this time.

5.2 Validation Status of the ICE Test Method

The following is a synopsis of the information in the final ICCVAM BRD (**Appendix F**), which reviews the available data and information for the ICE test method. The ICCVAM BRD describes the

current validation status of the ICE test method, including what is known about its reliability and accuracy, the scope of the substances tested, and standardized protocols for the validation study.

5.2.1 Test Method Description

The ICE test method is an *in vitro* model that provides short-term maintenance of the chicken eye. In the ICE test method, damage by the test substance is assessed by determination of corneal swelling, opacity, and fluorescein retention. While the latter two parameters involve a qualitative assessment, analysis of corneal swelling provides for a quantitative assessment. Each measurement is either converted into a quantitative score used to calculate an overall irritation index, or assigned a qualitative categorization that is used to assign an *in vitro* ocular irritation classification. Either of these outcomes can then be used to predict the *in vivo* ocular irritation potential of a test substance.

5.2.2 Validation Database

No new ICE data were obtained after the ICCVAM evaluation of the ICE test method for identifying ocular corrosives and severe irritants (ICCVAM 2006c). Therefore, the same database was used in the current evaluation. It is composed of 175 substances representing a wide variety of chemical and product classes. However, of the 175 substances, 85 (including formulations of unidentified composition) could not be assigned a specific chemical class.

Detailed *in vivo* data were necessary to calculate the appropriate EPA, EU, FHSA, and GHS ocular hazard classifications (EPA 2003; EU 2001; FHSA 2005; UN 2007) (**Appendix F**). These data consist of cornea, iris and conjunctiva scores for each animal at 24, 48, and 72 hours and/or assessment of the presence or absence of lesions at 7, 14, and 21 days. Thus, some of the test substances for which there was only limited *in vivo* data could not be used to evaluate test method accuracy and reliability. In order to maximize the number of substances included in these analyses, "proportionality" criteria (i.e., FHSA-20% and FHSA-67%) were applied for the purpose of assigning an FHSA classification for test results that would require additional testing according to the FHSA sequential testing strategy (see **Section 2.2.2**).

5.2.3 Test Method Accuracy

Identification of All Ocular Hazard Categories

The ability of the ICE test method to identify all categories of ocular irritation potential was evaluated for the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).[15] As indicated in **Table 5-1**, overall correct classifications ranged from 59% (83/141) to 77% (118/153) depending on the classification system used when evaluating the entire database.

[15] The FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test does not distinguish between ocular corrosives/severe irritants and less severe irritants. For this reason, an avaluation of the ICE test method to identify all ocular hazard categories using the FHSA classification system is not possible.

Table 5-1 Evaluation of the Performance of the ICE Test Method in Predicting Ocular Irritant Classes Compared to the *In Vivo* Rabbit Eye Test Method, as Defined by the EPA, EU, and GHS Classification Systems[1]

	Overall Correct Classification	Severe[2]		Moderate[3]			Mild[4]			Not Labeled[5]	
		Actual	Under	Over	Actual	Under	Over	Actual	Under	Over	Actual
EPA	62% (87/140)	48% (13/27)	52% (14/27)	31% (5/16)	50% (8/16)	19% (3/16)	29% (11/38)	53% (20/38)	18% (7/38)	22% (13/59)	78% (46/59)
EU	77% (118/153)	59% (19/32)	41% (13/32)	18% (5/28)	57% (16/28)	25% (7/28)	NA	NA	NA	11% (10/93)	89% (83/93)
GHS	59% (83/141)	52% (15/29)	48% (14/29)	36% (8/22)	36% (8/22)	28% (6/22)	18% (2/11)	73% (8/11)	9% (1/11)	34% (27/79)	66% (52/79)

Abbreviations: EPA = U.S. Environmental Protection Agency; EU = European Union; GHS = Globally Harmonized System; ICE = isolated chicken eye; NA = not applicable.

[1] EPA classification system (EPA 2003); GHS classification system (UN 2007); EU classification system (EU 2001).

[2] Severe = EPA Category I; GHS Category 1; EU R41.

[3] Moderate = EPA Category II; GHS Category 2A; EU R36.

[4] Mild = EPA Category III; GHS Category 2B.

[5] Not Labeled = EPA Category IV; EU Not Labeled; GHS Not Classified.

Distinguishing Substances Not Labeled as Irritants from All Other Hazard Categories
The ability of the ICE test method to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other ocular hazard categories (i.e., EPA Category I, II, III; EU R41, R36; FHSA Irritant; GHS Category 1, 2A, 2B) as defined by the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007) was also evaluated.

As indicated in **Table 5-2**, overall accuracy for the identification of substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, FHSA Not Labeled, GHS Not Classified) from all other categories ranged from 78% (110/141) to 85% (130/153) depending on the hazard classification system used. The false negative rates ranged from 6% (4/62) to 22% (13/60) depending on the hazard classification system used. The lowest false negative rate (6%) was noted for the GHS system, followed by 9% (7/76) for the FHSA-67% system, 12% (10/84) for the FHSA-20% system, 14% (11/81) for the EPA system, and 22% (13/60) for the EU system. However, at least one of these false negatives is classified as an ocular corrosive and severe irritant based on Draize rabbit eye test data (n = 1 each for the EPA and GHS systems and n = 6 for the EU system).

Table 5-2 Accuracy of the ICE Test Method for Distinguishing Substances Not Labeled as Irritants[1] from All Other Irritant Classes

	N	Accuracy		Sensitivity		Specificity		False Positive Rate		False Negative Rate	
		%	No.	%	No.	%	No.	%	No.	%	No.
EPA	140	83	116/140	86	70/81	78	46/59	22	13/59	14	11/81
GHS	141	78	110/141	94	58/62	66	52/79	34	27/79	6	4/62
EU	153	85	130/153	78	47/60	89	83/93	11	10/93	22	13/60
FHSA-20%	146	83	121/146	88	74/84	76	47/62	24	15/62	12	10/84
FHSA-67%	138	84	116/138	91	69/76	76	47/62	24	15/62	9	7/76

Abbreviations: EPA = U.S. Environmental Protection Agency; EU = European Union; FHSA = U.S. Federal Hazardous Substances Act; GHS = Globally Harmonized System; ICE = isolated chicken eye; N = number of substances included in this analysis; No. = data used to calculate the percentage.

[1] GHS classification system (UN 2007): Not Classified vs. Category 1/2A/2B.
EPA classification system (EPA 2003): Category IV vs. Category I/II/III.
EU classification system (EU 2001): Not Labeled vs. R41/R36.
FHSA classification system (FHSA 2005): Not Labeled vs. Irritant.

5.2.4 Test Method Reliability

Interlaboratory Reproducibility
Quantitative and qualitative evaluations of ICE test method reliability have been conducted previously (ICCVAM 2006c). However, additional qualitative analyses of interlaboratory reproducibility were conducted to evaluate the extent of agreement of ICE hazard classifications among the four laboratories participating in the interlaboratory validation study (Balls et al. 1995). As was done for the accuracy evaluation, these qualitative evaluations of reproducibility were based on (1) the use of the ICE test method for identifying all ocular hazard categories according to the EPA, EU, or GHS systems, and (2) the use of the ICE test method to distinguish substances not labeled as irritants (i.e., EPA Category IV, EU Not Labeled, GHS Not Classified) from all other ocular hazard categories (i.e., EPA Category I, II, or III; EU R41 or R36; GHS Category 1, 2A, or 2B). Given that the performance of the ICE test method was similar for the EPA and FHSA classification systems, additional reliability analyses were not conducted for the FHSA classification system.

Using the first approach (i.e., identifying all ocular hazard categories), there was 100% agreement among the four laboratories for a majority of the Draize ocular corrosives and severe irritants for all three classification systems, whether the substances were correctly identified or underclassified by the ICE test method. (For example, for the EPA system, there was 100% agreement for 70% [7/10] of the correctly identified Category I substances.) There was 100% agreement among the four laboratories for at least 50% (3/6 to 3/5) of the correctly identified moderate ocular irritants (EPA Category II, GHS Category 2A, EU R36). For the mild ocular irritants (EPA Category III, GHS Category 2B), there was 100% agreement among the four laboratories for 0% (0/2) to 13% (1/8) of the correctly identified substances. The four laboratories had only 50% agreement for 50% (4/8 or 1/2) of these substances for the EPA and GHS classification systems.

Among the four laboratories, a majority of the substances not classified as irritants based on Draize results (i.e., EPA Category IV, EU Not Labeled, GHS Not Classified) were overclassified by the ICE test method. The four laboratories had at least 75% agreement for all but two of these substances. For example, there was at least 75% agreement for 85% (11/13) of the GHS Not Labeled substances overclassified by the ICE test method. The four laboratories had at least 75% agreement for 76% (13/17) of the EU Not Labeled substances, whether they were correctly identified or overclassified by the ICE test method. For example, there was at least 75% agreement for 77% (7/9) of the EU Not Labeled substances that were correctly identified and 75% (6/8) of those overclassified by the ICE test method.

Using the second approach (i.e., distinguishing substances not labeled as irritants from all other ocular hazard categories), there was 100% agreement among the four laboratories for 61% (36/59) to 75% (44/59) of the substances included in the Balls et al. (1995) study.

There was 100% agreement among the four laboratories for 81% (38/47) of the substances correctly identified as irritants according to the EPA system (i.e., Category I, II, or III). While none of the EPA Category IV substances was correctly identified by the ICE test method, there was 75% agreement among the four laboratories for both of the Category IV substances that were overpredicted by the ICE test method.

The four laboratories had 100% agreement for 87% (33/38) of the substances correctly identified as irritants according to the GHS system (i.e., Category 1, 2A, or 2B). While only one of the GHS substances not labeled as irritants was correctly identified by the ICE test method (for which there was 75% agreement among the laboratories), there was at least 75% agreement among the four laboratories for 85% (11/13) of the GHS substances not labeled as irritants that were overpredicted by the ICE test method.

There was 100% agreement among the four laboratories for 85% (22/26) of the substances correctly identified as irritants according to the EU system (i.e., R36 or R41). The laboratories had at least 75% agreement for 77% (7/9) of the substances correctly identified as Not Labeled.

The final ICCVAM BRD (**Appendix F**) provides a comprehensive summary of the current validation status of the ICE test method, including what is known about its reliability and accuracy, and the scope of the substances tested. Raw data for the ICE test method will be maintained for future use, so that these performance statistics may be updated as additional information becomes available.

5.2.5 Animal Welfare Considerations

The ICE test method refines animal use. Because these animals are being humanely processed for nonlaboratory purposes, the testing procedure inflicts no additional pain or distress on animals. Substances that are identified as corrosive or severe irritants *in vitro* are excluded from *in vivo* testing.

The ICE test method can also reduce animal use. The test method utilizes animal species routinely raised as a food source in large numbers to replace the need for laboratory animals.

6.0 The Isolated Rabbit Eye Test Method

The IRE test method is an *in vitro* eye irritation test method using eyes from rabbits that have been euthanized for other research purposes or are byproducts from processing plants. In the IRE test method, the treated eye may be evaluated for corneal opacity, corneal swelling, fluorescein penetration, and effects on the corneal epithelium at various times over a four-hour observation period.

ICCVAM previously evaluated the validation status of the IRE test method as an *in vitro* alternative to the Draize rabbit eye test to identify ocular corrosives and severe irritants (i.e., those that induce irreversible ocular damage; EPA Category I, EU R41, GHS Category 1) and determined that the reproducibility and accuracy was **not** sufficient to support its use for this purpose (ICCVAM 2006e). In the current evaluation, ICCVAM evaluated the validation status of the IRE test method as an *in vitro* alternative to the Draize rabbit eye test for identifying nonsevere ocular irritants (i.e., those that induce reversible ocular damage [EPA Category II and III; EU R36; GHS Category 2A and 2B]) and substances not labeled as irritants (i.e., EPA Category IV; EU Not Labeled; FHSA Not Labeled; GHS Not Classified) according to the EPA, EU, FHSA, and GHS classification systems (EPA 2003; EU 2001; FHSA 2005; UN 2007).

6.1 ICCVAM Recommendations

6.1.1 ICCVAM Recommendations: Test Method Usefulness and Limitations

Evaluation as a Screening Test to Identify All Ocular Hazard Categories

There are insufficient data using all four recommended IRE endpoints (i.e., corneal opacity, corneal swelling, fluorescein penetration, and effects on the corneal epithelium) in a single study to assess test method accuracy and reliability. Among the studies that included all four recommended IRE endpoints, decision criteria are focused on distinguishing ocular corrosives and severe irritants from all other ocular hazard categories (i.e., moderate and mild irritants and substances not labeled as irritants) and do not specify decision criteria for each ocular hazard category. For these reasons, an adequate evaluation of the IRE test method for its ability to identify all ocular hazard categories is not feasible at this time.

Evaluation as a Screening Test to Identify Ocular Corrosives and Severe Irritants

The available validation database for the IRE test method has not changed since the original ICCVAM evaluation (ICCVAM 2006d). Therefore, the original ICCVAM recommendation for the use of the IRE test method to identify substances as ocular corrosives and severe irritants remains unchanged:

> The use of the IRE test method for screening and identifying ocular corrosives and severe irritants (i.e., EPA Category I, GHS Category 1, EU R41) in a tiered-testing strategy, as part of a weight-of-evidence approach, is **not** recommended (ICCVAM 2006e).

Independent Peer Review Panel Conclusions and Recommendations

The Panel concluded that there are insufficient data from all four recommended IRE test method endpoints (i.e., corneal opacity, fluorescein penetration, corneal swelling, and effects on the corneal epithelium) to evaluate the accuracy and reliability of the test method when all four endpoints are evaluated in a single study. Therefore, the Panel recommended that additional optimization and validation studies be conducted to further evaluate the relevance and reliability of the IRE test method, and in turn develop more definitive recommendations.

6.1.2 ICCVAM Recommendations: IRE Test Method Protocol

An ICCVAM-recommended test method protocol for the IRE test method that should be used for all future studies is included as an appendix to this report (**Appendix B**). The recommended protocol

remains unchanged from the previous ICCVAM evaluation (ICCVAM 2006e) and includes all four recommended IRE endpoints that should be measured: maximal corneal opacity (opacity × area), maximal corneal swelling, fluorescein penetration (intensity × area) and assessment of epithelial integrity (0.5, 1, 2, 3, and 4 hours).

Independent Peer Review Panel Conclusions and Recommendations

The Panel recommended that there should be rigid criteria specifying the handling and storage of the eyes. The Panel emphasized the need for control of the length of time between death and study initiation to account for any postmortem effects on the eye and criteria for appropriate inclusion/exclusion of ocular tissue. The Panel further emphasized the importance of criteria on test article administration/washout (e.g., viscous substances).

6.1.3 ICCVAM Recommendations: Future Studies for the IRE Test Method

To further the use of this test method and to evaluate the use of the IRE test method as a potential replacement for the Draize rabbit eye test or for the identification of all ocular hazard categories (i.e., EPA Category I, II, III, IV; GHS Category 1, 2A, 2B, Not Classified; FHSA Irritant, Not Labeled; EU R41, R36, Not Labeled), ICCVAM recommends additional studies be considered and undertaken.

- Additional evaluation studies should be conducted to increase the current IRE database and optimize the IRE test method decision criteria. Once these studies are conducted, ICCVAM recommends that additional validation studies be conducted to further evaluate the relevance and reliability of the IRE test method.
- ICCVAM recommends that a histopathological evaluation of the corneal tissue, using standardized procedures, be included when the IRE test method is conducted. Such data will allow for development of decision criteria and future assessments on the usefulness of this endpoint for classifying and labeling substances, especially those that may otherwise produce borderline or false negative results.
- ICCVAM encourages users to provide all data that are generated from future studies, as they could be used to further characterize the usefulness and limitations of the IRE test method for the identification of all ocular hazard categories.

Independent Peer Review Panel Conclusions and Recommendations

The Panel recommended a validation study to compare the utility of shipped rabbit eyes versus freshly collected rabbit eyes. Specifically, the Panel recommended inclusion of the study of shipping effects on ocular tissues into the planned validation study by GlaxoSmithKline and SafePharm. The Panel reiterated its concerns that there should be rigid criteria on the handling and storage of the eyes. In addition, the Panel recommended development of appropriate inclusion/exclusion criteria for eyes. Finally, the Panel recommended that criteria on test article administration/washout (e.g., viscous substances) should be developed.

6.1.4 ICCVAM Recommendations: Performance Standards for the IRE Test Method

Given that there are insufficient data using all four recommended IRE endpoints (i.e., corneal opacity, corneal swelling, fluorescein penetration, and effects on the corneal epithelium) in a single study to assess test method accuracy and reliability, ICCVAM recommends that the development of performance standards for the IRE test method is not warranted at this time.

6.2 Validation Status of the IRE Test Method

The IRE BRD (ICCVAM 2006d) describes the current validation status of the IRE test method, including what is known about its reliability and accuracy, the scope of the substances tested, and standardized protocols for the validation study.

6.2.1 Test Method Description

The IRE test method was developed by Burton and his colleagues at Unilever Research Laboratory, Colworth, United Kingdom, as an *in vitro* alternative to the Draize rabbit eye test for the assessment of eye irritation (Burton et al. 1981). In the IRE test method, liquid test substances are spread using a syringe, and solids are pulverized and applied as a powder over the corneas of enucleated rabbit eyes. The principal advantages of this test method are that the animals are euthanized prior to ocular irritancy testing (i.e., eyes from animals used for other toxicological purposes or from the food chain can be used) and testing is performed on the cornea, which is the part of the eye that is generally given the highest weight for scoring ocular irritancy in the Draize rabbit eye test. The effects of the test substance on the cornea of the isolated eye are measured quantitatively as an increase in thickness (swelling); subjectively as scores for corneal opacity, the area of corneal involvement, and fluorescein penetration; and descriptively as morphological changes to the corneal epithelium. However, the number of ocular parameters and the number of time points measured varies from study to study.

Two additional refinements of the IRE test method may be incorporated into the protocol or used *ad hoc* to supplement existing data. One is histopathological evaluation to confirm or identify the extent of irritancy at the cellular level, especially when the degree of irritancy falls between moderate and severe. Another is confocal microscopy to determine the extent and depth of ocular injury (Maurer et al. 2002). Many studies using the IRE test method evaluate single or multiple ocular endpoints at various times and then assign irritancy classifications to the substances tested (CEC 1991; Köeter and Prinsen 1985; Cooper et al. 2001; Jones et al. 2001), while others use mean data from one or more ocular endpoints assessed at various times after application of the test substance, typically 0.5 to 4 hours (Balls et al. 1995; Gettings et al. 1996). One protocol for the IRE test method was designed to specifically identify severe eye irritants (Guerriero et al. 2004). In this study, cut-off values for each ocular parameter tested were predetermined. If these cut-off values were achieved or exceeded in any single parameter over a period of 0.5 to 4 hours, including a significant change in the corneal epithelium, the test substance was classified as a severe eye irritant with potential to cause serious or irreversible damage to the human eye.

6.2.2 Validation Database

The available validation database for the IRE test method has remained unchanged since the original ICCVAM evaluation (ICCVAM 2006d). A total of 149 substances were evaluated in five studies, of which 25 were commercial products or formulations (ICCVAM 2006d). The chemical classes tested included but were not limited to alcohols, amides, amines, carboxylic acids, esters, ethers, formulations, heterocyclic, ketones, onium compounds, and sulfur compounds. The commercial products or formulations tested were skin cleansers, soaps, shampoos, conditioners, surfactants, and solvents.

Detailed *in vivo* data consisting of cornea, iris, and conjunctiva scores for each animal at 24, 48, and 72 hours and/or assessment of the presence or absence of lesions at 7, 14, and 21 days were necessary to calculate the appropriate EPA, EU, and GHS ocular hazard classifications (EPA 2003; EU 2001; UN 2007) (ICCVAM 2006d). Thus, some of the test substances for which there were only limited *in vivo* data could not be used to evaluate test method accuracy and reliability.

6.2.3 Test Method Accuracy

There are insufficient data using all four recommended IRE endpoints (i.e., corneal opacity, corneal swelling, fluorescein penetration, and effects on the corneal epithelium) in a single study to assess test method accuracy and reliability. Among the studies that included all four recommended IRE endpoints, decision criteria are focused on distinguishing ocular corrosives and severe irritants from all other ocular hazard categories (i.e., moderate and mild irritants and substances not labeled as irritants) and do not specify decision criteria for each ocular hazard category. For these reasons, an

adequate evaluation of the IRE test method for its ability to identify all ocular hazard categories is not feasible at this time.

6.2.4 Test Method Reliability

Due to the lack of quantitative IRE test method data for replicate experiments within an individual laboratory, an evaluation of the intralaboratory repeatability and reproducibility of the IRE test method could not be conducted. However, multilaboratory qualitative and quantitative IRE test method data were available for a collaborative study by the CEC (1991) and a validation study conducted by Balls et al. (1995). Three laboratories participated in the CEC (1991) collaborative study and four laboratories participated in the Balls et al. (1995) validation effort. In the CEC (1991) study, each substance tested was assigned a EU classification (R41, R36, or Not Labeled) based on *in vivo* rabbit eye test results. However, due to the lack of individual Draize rabbit eye test scores, a reliability assessment for the CEC (1991) study using the EPA (EPA 2003) or GHS (UN 2007) classification systems was not possible. The Balls et al. (1995) data were used for an evaluation of the interlaboratory reproducibility of the IRE test method according to the EPA, EU, and GHS classification systems (EPA 2003; EU 2001; UN 2007).

6.2.5 Animal Welfare Considerations

The IRE test method reduces animal use by obtaining eyes from rabbits raised for food or rabbits sacrificed after use in other laboratory procedures that do not adversely affect the eye. The IRE test method is a refinement of the *in vivo* rabbit eye test in that the animals are sacrificed prior to application of the test substance and, therefore, the animals do not experience pain and suffering when an ocular irritant is directly applied to the eye. Furthermore, because the IRE test method was adapted from the Draize rabbit eye test specifically to reduce the need for live animals for ocular irritation testing, pain and suffering of the animals is eliminated and the overall number of animals needed for ocular toxicity screening is reduced.

Although rabbits are required as a source of corneas for the IRE test method, only rabbits sacrificed for food or used for other laboratory purposes are used as eye donors (i.e., no live animals are specifically sacrificed for use in this test method).

7.0 ICCVAM Consideration of Public, SACATM, and ICATM Comments

The ICCVAM evaluation process incorporates a high level of transparency. This process is designed to provide numerous opportunities for stakeholder involvement, including submitting written public comments and providing oral comments at ICCVAM independent peer review panel meetings and SACATM meetings. **Table 7-1** lists the nine opportunities for public comments that were provided during the ICCVAM evaluation of the validation status of alternative ocular safety testing methods and approaches. The number of public comments received in response to each of the opportunities is also indicated. Thirty-seven comments were submitted. Comments received in response to or related to *Federal Register* notices (**Appendix H**) are also available on the NICEATM-ICCVAM website.[16] The following sections, delineated by *Federal Register* notice, briefly discuss the public comments received.

Table 7-1 Opportunities for Public Comments

Opportunities for Public Comments	Date	Number of Public Comments Received
70 FR 13512: Request for Data on Non-Animal Methods and Approaches for Determining Skin and Eye Irritation Potential of Antimicrobial Cleaning Product Formulations; Request for Nominations for an Independent Expert Panel	March 21, 2005	0
72 FR 26396: Request for Data on the Use of Topical Anesthetics and Systemic Analgesics for *In Vivo* Eye Irritation Testing	May 9, 2007	1
72 FR 31582: Request for Ocular Irritancy Test Data From Human, Rabbit, and *In Vitro* Studies Using Standardized Testing Methods	June 7, 2007	0
73 FR 18535: Non-Animal Methods and Approach for Evaluating Eye Irritation Potential for Antimicrobial Cleaning Products (AMCPs): Request for Nominations for an Independent Expert Panel and Submission of Relevant Data	April 4, 2008	12
74 FR 14556: Announcement of an Independent Scientific Peer Review Panel on Alternative Ocular Safety Testing Methods; Availability of Draft Background Review Documents (BRD); Request for Comments	March 31, 2009	8
74 FR 19562: Meeting of the Scientific Advisory Committee on Alternative Toxicological Methods (SACATM)	April 29, 2009	2
Independent Scientific Peer Review Panel Meeting: Alternative Ocular Safety Testing Methods	May 19–21, 2009	12
SACATM Meeting, Arlington Hilton, Arlington, VA	June 25–26, 2009	2
74 FR 33444: Independent Scientific Peer Review Panel Report: Evaluation of the Validation Status of Alternative Ocular Safety Testing Methods and Approaches; Notice of Availability and Request for Public Comments	July 13, 2009	0

[16] Available at http://ntp-apps.niehs.nih.gov/iccvambp/searchPubCom.cfm

7.1 Public Comments in Response to 70 FR 13512 (March 21, 2005) Request for Data on Non-Animal Methods and Approaches for Determining Skin and Eye Irritation Potential of Antimicrobial Cleaning Product Formulations; Request for Nominations for an Independent Expert Panel

NICEATM requested (1) submission of data that would assist in evaluating the validation status of non-animal methods and approaches used for determining the skin and eye irritation potential of AMCP formulations to meet regulatory hazard classification and labeling purposes and (2) nominations of expert scientists to serve as members of an independent peer review panel.

No data or nominations were received in response to this *Federal Register* notice.

7.2 Public Comments in Response to 72 FR 26396 (May 9, 2007) Request for Data on the Use of Topical Anesthetics and Systemic Analgesics for *In Vivo* Eye Irritation Testing

NICEATM requested submission of (1) data and information on the use of topical anesthetics and systemic analgesics for alleviating pain and distress in rabbits during eye irritation testing and (2) information about other procedures and strategies that may reduce or eliminate pain and distress associated with *in vivo* eye irritation methods.

NICEATM received 1 comment in response to this *Federal Register* notice. This comment was not relevant to *in vitro* ocular safety test methods.

7.3 Public Comments in Response to 72 FR 31582 (June 7, 2007) Request for Ocular Irritancy Test Data From Human, Rabbit, and *In Vitro* Studies Using Standardized Testing Methods

NICEATM requested data on substances tested for ocular irritancy in humans, rabbits, and/or *in vitro* to be used to:

- Review the state of the science in regard to the availability of accurate and reliable *in vitro* test methods for assessing the range of potential ocular irritation activity, including whether ocular damage is reversible or not
- Expand NICEATM's high-quality ocular toxicity database. *In vitro* test methods for which data are sought include but are not limited to (1) the bovine corneal opacity and permeability test, (2) the isolated rabbit eye test, (3) the isolated chicken eye test, and (4) the hen's egg test–chorioallantoic membrane.

No data or information were received in response to this *Federal Register* notice.

7.4 Public Comments in Response to 73 FR 18535 (April 4, 2008) Non-Animal Methods and Approach for Evaluating Eye Irritation Potential for Antimicrobial Cleaning Products (AMCPs): Request for Nominations for an Independent Expert Panel and Submission of Relevant Data

NICEATM requested the following:

- Nominations of expert scientists to serve as members of an independent peer review panel
- Submission of relevant data and information on AMCPs or related substances obtained from (1) human testing or experience, including reports from accidental exposures, and (2) rabbit testing using the standard eye test or the LVET

- *In vitro* ocular safety test methods such as the bovine corneal opacity and permeability test method, the Cytosensor Microphysiometer test method, and the EpiOcular test method, including data supporting the accuracy and reproducibility of these methods

In response to this *Federal Register* notice, NICEATM received 12 comments, including nominations of 20 potential panelists. The nominees were included in the database of experts from which the Panel was selected. No additional data were received.

7.5 Public Comments in Response to 74 FR 14556 (March 31, 2009) Announcement of an Independent Scientific Peer Review Panel on Alternative Ocular Safety Testing Methods; Availability of Draft Background Review Documents (BRD); Request for Comments

NICEATM requested public comments on the draft BRDs, SRDs, and draft ICCVAM test method recommendations that were provided to an independent scientific peer review panel meeting (May 19–21, 2009). These documents summarized the current validation status of several test methods and testing strategies for identifying potential ocular irritants. The test methods and testing strategies included the following:

- A testing strategy that proposes the use of three *in vitro* test methods to assess the eye irritation potential of AMCPs
- Four *in vitro* test methods for identifying moderate (EPA Category II, UN Globally Harmonized System of Classification and Labelling of Chemicals [GHS] Category 2A) and mild (EPA Category III, GHS Category 2B) ocular irritants and substances not classified as ocular irritants (EPA Category IV, GHS Not Classified)
- The *in vivo* LVET
- A proposal for the routine use of topical anesthetics, systemic analgesics, and earlier humane endpoints to avoid and minimize pain and distress during *in vivo* ocular irritation testing

NICEATM received 20 comments in response to this *Federal Register* notice. Eight written comments were received before the Panel meeting, and 12 oral comments were provided at the Panel meeting. Of these comments, 10 were relevant to *in vitro* ocular safety test methods.

Public Responses (written)

HET-CAM—Two written comments were relevant to the HET-CAM test method.

Comment:
One commenter emphasized the importance of establishing one specific protocol and specific endpoints to be used for the HET-CAM test method. Based on a database of 145 substances tested in both the HET-CAM and Draize test methods, the commenter reported that the HET-CAM test method was not useful to identify water-soluble substances as severe irritants in a tiered-testing strategy. However, the HET-CAM might be applicable for excluding severe ocular irritants among water-insoluble substances.

ICCVAM Response:
ICCVAM recommends that additional studies should be conducted to further optimize the HET-CAM prediction models and the decision criteria that would be used to identify ocular corrosives and severe irritants (EPA Category I, EU R41, GHS Category 1). Such studies could potentially improve the usefulness of the HET-CAM test method for identifying these types of substances.

Comment:
Another commenter made the following comments on the HET-CAM draft BRD: (1) the terminology describing the endpoints used in the HET-CAM test method needs to be clarified, (2) the HET-CAM validation database appears to have some inconsistencies with regard to chemical class, (3) the HET-CAM validation database needs to be evaluated by solubility, and (4) the method for counting the days of embryonic development needs to be clarified.

ICCVAM Response:
The text was clarified and supporting references were provided in the final BRD (**Appendix E**) for the endpoints used in the HET-CAM test method. With regard to chemical class, the classifications in the BRD are based on the National Library of Medicine MeSH chemical classification system. Additional details for counting the days of embryonic development were provided in the final BRD.

ICE— One written comment was relevant to the ICE test method.

Comment:
The main point provided by the commenter is that the selection criteria set forth by ICCVAM for classification purposes of substances tested with the ICE test method are inappropriate. The commenter states that additional data from studies that were terminated earlier than 21 days after treatment or compounds lacking an *in vivo* eye irritation study because of proven *in vivo* skin corrosivity should be considered. The commenter also addressed the variability of the Draize rabbit eye test and expressed concern that the Draize rabbit eye test (i.e., OECD TG 405) has no standardized exposure regimen.

ICCVAM Response:
The performance of the ICE test method was reevaluated after including skin corrosivity test results (n = 8) and corrections to the classification of specific test substances, where appropriate based on the additional data and information provided by the commenter. These changes are reflected in the ICE final BRD (**Appendix F**). However, the addition and modification of these test results did not significantly impact the performance of the ICE test method or the conclusions and recommendations of the Panel or ICCVAM.

HCE— One written comment was specific to the human corneal epithelial cell (HCE) model.

Comment:
The commenter provided comments on an ATLA journal article (Eskes et al. 2005) that described the human corneal epithelial cell (HCE) model and a list of key references omitted from that review.

ICCVAM Response:
Although the HCE model was not part of the current evaluation, ICCVAM welcomes comments on alternative *in vitro* test methods at any time. ICCVAM encourages the submission of data for the HCE model for future evaluation of its validation status.

Public Responses, Oral
Twelve oral public comments were provided at the Panel meeting (May 19-21, 2009).

HET-CAM— One commenter remarked specifically on the HET-CAM test method.

Comment:
One commenter indicated that the false negatives using the EPA classification system, which are Not Classified using the GHS classification system, result because the EPA classification system categorizes substances based upon the most severe category observed among the test rabbits (i.e., hazard classification is not based on the majority classification among rabbits tested). The commenter noted that because the types of formulations regulated by EPA are not present in the database, the EPA classification system should not be given too much weight.

ICCVAM Response:
Until the GHS classification system is formally adopted, ICCVAM will continue to consider all relevant hazard classification systems (i.e., EPA, EU, and GHS) when evaluating the usefulness and limitations of an *in vitro* test method.

ICE— One commenter remarked specifically on the ICE test method.

Comment:
One commenter indicated that the variability of the ICE test method was similar to that of the Draize rabbit eye test. The commenter stated that the ICE test method should not be held to a higher standard than the Draize rabbit eye test and noted that the concordance among laboratories was reasonable.

ICCVAM Response:
All *in vitro* test methods are evaluated according to the *ICCVAM Guidelines for the Nomination and Submission of New, Revised, and Alternative Test Methods* (ICCVAM 2003), including a comparison to the currently accepted regulatory test method as a reference.

BCOP— Three commenters remarked specifically on the BCOP test method.

Comment:
One commenter indicated that the performance of the BCOP test method was unlikely to improve based on the lack of reproducibility with the Draize rabbit eye test in the mild and moderate categories. The commenter stated that results from Weil and Scala (1971) show that the extremes (i.e., corrosives/severe irritants and substances not labeled as irritants) are reproducible, but the mild and moderate levels of ocular irritation are highly variable. The commenter referenced the AMCP BRD that includes an analysis of the impact on the ocular hazard category when the results of a six-rabbit Draize test are randomly sampled for a three-rabbit test.

ICCVAM Response:
The Draize rabbit eye test (Draize et al. 1944) has a long history of demonstrated protection of public health and therefore, U.S. and international regulatory agencies currently use this test to identify potential ocular hazards. Alternatives are accepted only when they demonstrate the ability to provide equal or better protection than the reference test method. Given the uncertainty of the results associated with the BCOP test method for substances in the mild/moderate irritancy range, the BCOP test method cannot be considered a complete replacement at this time.

Comment:
A second commenter stated that damaged eyes are quickly removed and excluded from the BCOP test method and that Gautheron et al. (1992) used both fresh eyes and eyes maintained at 4ºC and found no differences in results. The commenter also asked the Panel to reconsider the use of a histopathology evaluation in the BCOP test method.

ICCVAM Response:
ICCVAM previously evaluated and recommended the BCOP test method for the identification of corrosive/severe ocular irritants (ICCVAM 2006e). In the current evaluation, ICCVAM, along with the Panel, recommends the BCOP test method for the identification of substances not labeled as irritants. Furthermore, the final ICCVAM recommendations state that a histopathological evaluation of the corneal tissue, using standardized procedures, should be included when the BCOP test method is conducted. Such data will allow for development of decision criteria and future assessments on the usefulness of this endpoint for classifying and labeling substances, especially those that may otherwise produce borderline or false negative results.

Comment:
A third commenter discussed the "top-down" (i.e., screening for corrosives/severe irritants) and "bottom-up" (i.e., screening for substances not labeled as irritants) approaches using the ICE and

BCOP test methods. The commenter stated that ECVAM is developing a paper to recommend the use of these proposed testing strategies for both ICE and BCOP, where substances could be tested in the BCOP or ICE test methods in order to identify corrosives/severe irritants or substances not labeled as irritants without using an animal test.

ICCVAM Response:
ICCVAM currently recommends the ICE and BCOP test methods for use in a tiered-testing strategy, where positive substances can be classified as ocular corrosives and severe irritants without the need for animal testing (ICCVAM 2006e). However, identification of nonsevere ocular irritants and substances not labeled as irritants would require another test that has been demonstrated as scientifically validated for identifying such substances.

Comment:
One commenter questioned the need for performance standards for the CM test method, given that the Panel did not recommend performance standards for the BCOP and ICE test methods.

ICCVAM Response:
The final ICCAM recommendations state that the development of performance standards for the CM test method is not warranted at this time.

7.6 Public Comments in Response to 74 FR 19562 (April 29, 2009) Meeting of the Scientific Advisory Committee on Alternative Toxicological Methods (SACATM)

NICEATM announced the SACATM meeting (June 25–26, 2009) and requested written and public oral comments on the agenda topics.

NICEATM received four comments. Two written comments were received before the meeting, and two oral comments were provided at the SACATM meeting. None of these comments were relevant to *in vitro* ocular safety test methods.

SACATM Response:
In general, SACATM was pleased with the Panel report. One SACATM member expressed the need for harmonization in the assessment of performance standards. Another SACATM member said the focus should be on the GHS system because it will ultimately be adopted. Another SACATM member expressed concern regarding the availability of the Cytosensor Microphysiometer.

7.7 Public Comments in Response to 74 FR 33444 (July 13, 2009) Independent Scientific Peer Review Panel Report: Evaluation of the Validation Status of Alternative Ocular Safety Testing Methods and Approaches; Notice of Availability and Request for Public Comments

NICEATM requested submission of written public comments on the independent scientific peer review panel report.

No public comments were received.

7.8 Comments Received from ICATM Validation Organizations

In accordance with the International Cooperation on Alternative Test Methods (ICATM), each participating organization (i.e., ECVAM, Health Canada, and JaCVAM) was given the opportunity to comment prior to finalizing these recommendations. All ICATM partners agreed with these recommendations with one exception noted from ECVAM regarding the usefulness and limitations of the BCOP test method (see **Appendix H4**). ECVAM agreed with ICCVAM that the BCOP test method should not be recommended for the identification of substances not labeled as irritants under the EPA and FHSA classification system. However, they did not agree with ICCVAM's concerns

about the underprediction that would occur with the use of the BCOP test method under the GHS classification system compared to the EPA and FHSA systems currently used in the United States. Rather, ECVAM expressed the view that the predictivity of a test method should be calculated independently for each classification, without regard to the nature, severity, and duration of eye injuries that were the basis for ICCVAM's concerns, and that serve as the basis for classification as eye hazards using current U.S. classification criteria. Thus, ECVAM considered the calculated predictivity of the BCOP test method for available test data (0% [0/97] false negatives) to support its use for identifying substances not labeled as irritants when compared strictly to the eye hazard criteria in the current GHS classification system. While ECVAM also noted that their recommendations would be in line with the ICCVAM Peer Review Panel, as stated in **Section 2.1.1**, the Peer Panel deliberations preceded the NICEATM evaluation of the GHS classification system that indicates an estimated 30% or more of substances requiring labeling for eye irritation hazard according to current U.S. hazard classification requirements will not be labeled as eye irritation hazards by the current GHS criteria. ECVAM disagrees with the ICCVAM concern that, "*the nature, severity, and duration of these eye injuries suggest the potential to cause human injury,"* because they state that there is no empirical evidence to substantiate that there should in fact be such a concern. While ICCVAM was not able to find any human accidental exposure data for the chemicals that will no longer be labeled as eye hazards, there also are no human exposure or test data to suggest that these chemicals, which produced significant eye injuries in rabbits, will not produce significant injuries to human eyes.

NICEATM has searched numerous databases (i.e., OSHA, CPSC, EPA) for human eye injury data for these chemicals, but no relevant data have been identified. U.S. Federal law requires agencies to determine that new test methods recommended by ICCVAM generate data that are at least equivalent to data generated by current test methods required or recommended by each agency for hazard identification purposes. Therefore, until the issues associated with the GHS system as outlined above are further discussed, ICCVAM is deferring final recommendations on the usefulness and limitations of using BCOP as a screening test to identify substances not labeled as irritants according to the GHS classification system. At such time that relevant human testing or exposure data becomes available, ICCVAM will revisit this issue. In the meantime, the Scientific Advisory Committee on Alternative Toxicological Methods will be asked to comment at their June 2010 meeting about the extent that reversible chemically induced eye injuries in rabbits might indicate the potential for injury to humans. Minutes of this meeting will be available on the NTP website at: http://ntp.niehs.nih.gov/index.cfm?objectid=720165EC-BDB7-CEBA-F517D1DEE4D7D129.

ICCVAM Evaluation Timeline

This page intentionally left blank

ICCVAM Evaluation Timeline

June 7, 2007 — *Federal Register* Notice (72 FR 31582) – Request for Ocular Irritancy Test Data From Human, Rabbit, and In Vitro Studies Using Standardized Test Methods.

November 26, 2007 — *Federal Register* Notice (72 FR 65964) – Availability of Test Method Evaluation Report and Final Background Review Documents on In Vitro Ocular Toxicity Test Methods for Identifying Severe Irritants and Corrosives; ICCVAM Test Method Recommendations to Federal Agencies.

April 4, 2008 — *Federal Register* Notice (73 FR 18535) – Non-Animal Methods and Approach for Evaluating Eye Irritation Potential for Antimicrobial Cleaning Products (AMCPs): Request for Nominations for an Independent Expert Panel and Submission of Relevant Data. Included request for information on AMCPs or related substances from:

1. Human testing or accidental exposures
2. The standard or low volume eye test
3. *In vitro* test methods (i.e., bovine corneal opacity and permeability, Cytosensor® Microphysiometer, EpiOcular test).

March 31, 2009 — *Federal Register* Notice (74 FR 14556) – Announcement of an Independent Scientific Peer Review Panel Meeting on the Evaluation of the Validation Status of Alternative Ocular Safety Testing Methods and Approaches; Availability of Draft Background Review Documents (BRD) and Summary Review Documents (SRD); Request for Comments.

May 19-21, 2009 — Independent Scientific Peer Review Panel holds a public meeting, with opportunity for public comments, at CPSC Headquarters in Bethesda, MD. The Panel was charged with reviewing the current validation status of alternative ocular safety testing methods and strategies, and commenting on the extent to which the information in the draft BRD and SRD supported the draft ICCVAM test method recommendations.

June 25-26, 2009	SACATM public meeting, SACATM and public comments on the draft Panel conclusions and recommendations.
July 13, 2009	*Federal Register* notice (74 FR 33444) – Independent Scientific Peer Review Panel Report: Evaluation of the Validation Status of Alternative Ocular Safety Testing Methods and Approaches: Notice of Availability and Request for Public Comments.
October 29, 2009	ICCVAM endorses the Test Method Evaluation Report, which includes the final Background Review Documents.

ICCVAM-Recommended Test Method Protocols

This page intentionally left blank

Appendix B1

ICCVAM-Recommended Protocol for Future Studies Using the Bovine Corneal Opacity and Permeability (BCOP) Test Method

This page intentionally left blank

Preface

This proposed protocol for measuring corneal damage was developed following a comprehensive test method evaluation process conducted by ICCVAM, which included an international independent scientific peer review of the validation status and scientific validity of the BCOP (ICCVAM 2006a,b). It is based primarily on information obtained from (1) the Institute for In Vitro Sciences, Inc. (IIVS), a nonprofit foundation that has performed the BCOP assay since 1997 in a Good Laboratory Practice (GLP)-compliant testing facility and (2) INVITTOX Protocol 124 (1999), which represents the protocol used for the European Community sponsored prevalidation study of the BCOP assay conducted in 1997–1998. Both of these protocols are based on the BCOP assay methodology first reported by Gautheron et al. (1992). Future studies using the BCOP test method could include further characterization of the usefulness or limitations of the BCOP in a weight-of-evidence approach for regulatory decision-making. Users should be aware that the proposed test method protocol could be revised based on any additional optimization and/or validation studies that are conducted in the future. ICCVAM recommends that test method users consult the NICEATM–ICCVAM website (http://iccvam.niehs.nih.gov/) to ensure use of the most current test method protocol.

1.0 Purpose and Applicability

The purpose of this protocol is to describe the procedures used to evaluate the potential ocular corrosivity or severe irritancy of a test substance as measured by its ability to induce opacity and increase permeability in an isolated bovine cornea. Effects are measured by (1) decreased light transmission through the cornea (opacity); (2) increased passage of sodium fluorescein dye through the cornea (permeability); and (3) evaluation of fixed and sectioned tissue at the light microscopic level, if applicable. The opacity and permeability assessments of the cornea following exposure to a test substance are considered individually and also combined to derive an *in vitro* irritancy score, which is used to classify the irritancy level of the test substance. Histological evaluation of the corneas can be useful for identifying damage in tissue layers that does not produce significant opacity or permeability.

The focus of this protocol is on the use of the BCOP test method for the detection of ocular corrosives and severe irritants, as defined by the U.S. Environmental Protection Agency (EPA; EPA 2003a), European Union (EU; EU 2001), and United Nations Globally Harmonized System (GHS) of Classification and Labelling of Chemicals (UN 2007). Substances other than ocular corrosives and severe irritants (e.g., substances not labeled as irritants and mild/moderate ocular irritants) have been tested using this protocol; however, the BCOP test method is not currently considered to be adequately validated for these classes of ocular irritancy as defined by EPA (2003a), EU (2001), and GHS (UN 2007).

2.0 Safety and Operating Precautions

All procedures with bovine eyes and bovine corneas should follow the institution's applicable regulations and procedures for handling animal substances, which include, but are not limited to, tissues and tissue fluids. Universal laboratory precautions are recommended, including the use of laboratory coats, eye protection, and gloves. If available, additional precautions required for specific study substances should be identified in the Material Safety Data Sheet for that substance.

3.0 Materials, Equipment, and Supplies

3.1 Source of Bovine Eyes

Eyes from cattle are obtained from an abattoir located within close proximity of the testing facility. The cattle type (breed not specified) can be cows, heifers, steers, or bulls. Because cattle have a wide range of weights depending on breed, age, and sex, there is no recommended weight for the animal at the time of sacrifice.

Eyes from very old cattle are not recommended because the corneas tend to have a greater horizontal corneal diameter and vertical corneal thickness that could affect assay performance (Doughty et al. 1995; Harbell J, personal communication). Additionally, eyes from calves are not recommended since their corneal thickness and corneal diameter are considerably less than that of eyes from adult cattle.

3.2 Equipment and Supplies

- Corneal holders[1]
- Dissection equipment (scissors, scalpels, forceps)
- Electric screwdriver
- Falcon tubes (50 mL)
- Incubator or water bath
- Liquinox (or equivalent)
- Microplate reader or UV/VIS spectrophotometer
- Micropipettors and pipette tips
- Opacitometer
- Petri dishes
- Plastic containers for collection and transport of eyes
- Sample tubes (5 mL, glass) for permeability determination
- Spatula
- Specialized window-locking ring screwdriver
- Standard tissue culture and laboratory equipment
- Sterile deionized water
- Syringes (10 mL) and blunt tip needles (19 Gauge)
- Vacuum pump
- Volumetric flasks
- 96 well plates (polystyrene) or cuvettes of an appropriate size for UV/VIS spectrophotometer

3.3 Chemicals

- Ethanol (200 proof, absolute, anhydrous, ACS/USP grade)
- Imidazole
- Penicillin
- Sodium chloride
- Sodium fluorescein
- Streptomycin

[1] Users should be aware of a proposed corneal holder developed by Ubels et al. (2002). The ICCVAM Test Method Evaluation Report (2006b) recommends, "Studies should be conducted to evaluate the impact of using a corneal holder that maintains normal curvature (e.g., the corneal mounting system designed by Ubels et al. 2002) on accuracy and/or reliability of the BCOP test method."

3.4 Solutions

Follow the manufacturer's recommendations with regard to storage temperature and shelf life of stock solutions. Prepare assay solutions volumetrically.

- 0.9% (w/v) NaCl in sterile deionized water (saline).
- 1X Hanks' Balanced Salt Solution with Ca^{++} and Mg^{++} (HBSS) containing 100 IU/mL penicillin and 100 µg/mL streptomycin.
- Dulbecco's Phosphate Buffered Saline (DPBS).
- Eagle's Minimum Essential Medium without phenol red containing 1% (v/v) Fetal Bovine Serum (complete MEM), warmed to 32˚C.
- Eagle's Minimum Essential Medium with phenol red containing 1% Fetal Bovine Serum (complete MEM with phenol red, used only for rinsing test substances), warmed to 32˚C.
- Sodium fluorescein (Na-fluorescein) diluted in DPBS to 4 mg/mL for liquid test articles or 5 mg/mL for solid test articles.

4.0 Test Substance Preparation

All test substance solutions should be prepared fresh on the day of use.

4.1 Nonsurfactant Liquid Test Substances

Liquid test substances are usually tested undiluted. However, if prescribed, dilutions of aqueous soluble test substances should be prepared in 0.9% sodium chloride.

4.2 Nonsurfactant Solid Test Substances

Nonsurfactant solid test substances should be prepared as 20% (w/v) solutions or suspensions in 0.9% sodium chloride.

4.3 Surfactants

Solid and concentrated liquid surfactants should be prepared and tested as a 10% (w/v, v/v) dilution or suspension in 0.9% sodium chloride.

4.4 Surfactant Preparations

Surfactant-based preparations (e.g., product formulations) are usually tested neat, or can be diluted in 0.9% sodium chloride, with justification of the selected dilution.

5.0 Controls

5.1 Negative Control

When testing a liquid substance at 100%, a concurrent negative control (e.g., 0.9% sodium chloride) is included to detect nonspecific changes in the test system, as well as to provide a baseline for the assay endpoints.

5.2 Solvent/Vehicle Control

When testing a diluted liquid, surfactant, or solid, a concurrent solvent/vehicle control is included to detect nonspecific changes in the test system, as well as to provide a baseline for the assay endpoints.

5.3 Positive Control

A known ocular irritant is included as a concurrent positive control in each experiment to verify that an appropriate response is induced. As the BCOP assay is being used to identify corrosive or severe irritants, ideally the positive control should be a reference substance that induces a severe response in this test method. However, to ensure that variability in the positive control response across time can be assessed, the magnitude of irritant response should not be excessive.

Examples of positive controls for liquid test substances are 1% sodium hydroxide or 10% dimethylformamide. An example of a positive control for solid test substances is 20% (weight to volume) imidazole in 0.9% sodium chloride solution.

5.4 Benchmark Substances (if appropriate)

Benchmark substances are useful for evaluating the ocular irritancy potential of unknown chemicals of a specific chemical or product class, or for evaluating the relative irritancy potential of an ocular irritant within a specific range of irritant responses. Appropriate benchmark substances should have the following properties:

- A consistent and reliable source(s)
- Structural and functional similarity to the class of the substance being tested
- Known physical/chemical characteristics
- Supporting data on known effects in the *in vivo* rabbit eye test
- Known potency in the range of the desired response

6.0 Experimental Design

6.1 Collection and Transport Conditions of Bovine Eyes

Bovine eyes are typically obtained from a local cattle abattoir, where the eyes are excised as soon as possible after sacrifice. Care should be taken to avoid damaging the cornea during the enucleation procedure. Eyes are collected in a suitable container in which they are immersed in HBSS containing the antibiotics penicillin (100 IU/mL) and streptomycin (100 µg/mL) The container is maintained on ice at all times throughout collection of the eyes and transportation to the testing facility (NOTE: antibiotics may not be necessary if the eyes are kept below 4°C throughout transport). The eyes are used within five hours of sacrifice.

Under conditions where contamination of the bovine eyes with yeast occurs, immersion of the eyes in HBSS containing fungizone should be evaluated.

6.2 Preparation of Corneas

a. Carefully examine all eyes macroscopically. Those exhibiting unacceptable defects, such as opacity, scratches, pigmentation, and neovascularization are rejected.

b. Carefully remove the cornea from each selected eye by making an incision with a scalpel 2 to 3 mm outside the cornea, then by cutting around the cornea with dissection scissors, leaving a rim of sclera to facilitate handling. Carefully peel off the iris and lens, ensuring no fragments of these tissues are remaining on the cornea. Take care to avoid damaging the corneal epithelium and endothelium during dissection.

c. Store the isolated corneas in a petri dish containing HBSS until they are mounted in holders. Examine the corneas before use, and discard those with defects.

d. Mount the corneas in holders (one cornea per holder) by placing the endothelial side of the cornea against the O-ring of the posterior chamber. Place the anterior chamber over the cornea and join the chambers together by tightening the chamber screws. Care should be taken not to shift the two chambers to avoid damaging the cornea.

e. Fill both chambers with fresh complete MEM (about 5 mL), always filling the posterior chamber first to return the cornea to its natural curvature. Care should be taken when adding or removing liquid from the posterior chamber to avoid the formation of bubbles and to minimize shear forces on the corneal endothelium.

f. Seal each chamber with plugs provided with the holders.

g. Incubate the holders in a vertical position at 32 ± 1°C for at least 60 minutes.

h. At the end of the initial 1-hour incubation period, examine each cornea for defects, such as tears or wrinkling. Discard corneas with any observed defects.

6.3 Control Cornea Selection and Opacity Reading

a. After the 1-hour incubation period, remove the medium from both chambers of each holder (anterior chamber first) and replace with fresh complete MEM.

b. Take and record an initial opacity reading for each cornea, using an opacitometer or equivalent instrument that has been appropriately calibrated according to the manufacturer's specifications. This initial opacity reading will be used to calculate the final opacity value for each cornea. The testing facility should ensure the opacitometer is functioning properly each day it is used.

c. Calculate the average opacity value for all corneas.

d. Select a minimum of three corneas with opacity values close to the average value for all corneas as negative (or solvent/vehicle) control corneas.

e. Corneas that display an initial opacity reading significantly greater (+ 2 standard deviations [SDs]) than the average opacity for all corneas in the batch of eyes collected the day of testing should not be used in the assay.

6.4 Treatment Groups

A minimum of three corneas are treated with each test substance solution or suspension. In addition, three corneas per assay are treated with the positive control and three corneas per assay are treated with the negative control. If a benchmark substance is used the day of testing, three corneas should be treated with the benchmark.

Different treatment methods are used depending on the physical nature and chemical characteristics (liquid or surfactant versus nonsurfactant solid) of the test substance. The controls used depend on which method is used.

6.5 Treatment of Corneas and Opacity Measurements

6.5.1 Closed chamber method for nonviscous to slightly viscous liquid test substances

a. Record the initial opacity readings and label each chamber with the appropriate control or test substance identification. Just prior to treatment, remove the medium from the anterior chamber through the dosing holes using an appropriate aspiration technique (e.g., blunt needle attached to a vacuum pump).

b. Add 0.75 mL of the control or test substance to the anterior chamber through the dosing holes using a micropipettor. The dosing holes are then resealed with the chamber plugs.

c. Rotate the holders such that the corneas are in a horizontal position. The holders should be gently tilted back and forth to ensure a uniform application of the control or test substance over the entire cornea.

d. Incubate the holders in a horizontal position at 32 ± 1°C for 10 ± 1 minutes. If other exposure times are used, justification must be provided.

e. Remove the control or test substance from the anterior chamber through the dosing holes and rinse the epithelium at least three times with approximately 2 to 3 mL of fresh complete MEM with phenol red. Perform one last rinse of the epithelium using fresh complete MEM. If it is not possible to remove all visible signs of the test substance, document the observation in the study notebook. Refill the anterior chamber with fresh complete MEM.

f. Perform a post-treatment opacity reading for each cornea and record the results. Observe each cornea visually and, if applicable, record pertinent observations (e.g., dissimilar opacity patterns, tissue peeling or residual test article).

g. Incubate the holders in a vertical (anterior chamber facing forward) position at 32 ± 1°C for 120 ± 10 minutes. If other post-exposure incubation times are used, justification should be provided.

h. Record a post-incubation opacity reading for each cornea, which will be used to calculate the final corneal opacity value. Observe each cornea visually and record pertinent observations in the study notebook. Special attention is taken to observe dissimilar opacity patterns, tissue peeling or residual test substance, etc.

6.5.2 Open chamber method for semiviscous and viscous liquid test substances and surfactant preparations

a. Record the initial opacity readings and label each chamber with the appropriate control or test article identification. Just prior to treatment, remove the medium from the anterior chamber through the dosing holes.

b. Remove the window-locking ring and glass window from all appropriate anterior chambers and place the holders into a horizontal position (anterior chamber facing up).

c. Add test substance to each chamber successively at a constant rate of 15 to 30 seconds between each chamber. Apply approximately 0.75 mL of the control or test substance (or enough test substance to completely cover the cornea) directly to the epithelial surface of the cornea using a micropipettor or other appropriate device, such as a spatula. Maintain the holders in a horizontal position (anterior chamber up).

d. If necessary, to aid in filling the pipette with substances that are viscous, the test article may first be transferred to a syringe. Insert the pipette tip of the positive displacement pipette into the dispensing tip of the syringe, so that the substance can be loaded into the displacement tip under pressure. Simultaneously, depress the syringe plunger as the pipette piston is drawn upwards. If air bubbles appear in the pipette tip, the test article should be expelled and the process repeated until the tip is filled without air bubbles. This method should be used for any substances that cannot be easily drawn into the pipette (e.g., gels, toothpastes, and face creams).

e. If necessary, immediately upon dosing, slightly tilt the holders to achieve a uniform application of the test article over the entire cornea.

f. After all of the chambers are dosed, replace the glass windows and window-locking rings.

g. Incubate the holders in a horizontal position at 32 ± 1°C for 10 ± 1 minutes. If other exposure incubation times are used, justification should be provided.

h. Prior to the end of the exposure period, remove the window-locking ring and glass window from each appropriate chamber.

i. At the completion of the exposure period, successively rinse each cornea in the exposure group according to the intervals that they were dosed. Using a syringe, add fresh complete MEM with phenol red to the inside wall of the anterior chamber creating a "whirlpool or vortex effect", which causes the test article to be rinsed off the cornea. Take special care not to spray the medium directly onto the cornea. Residual test article that cannot be removed from the cornea by the "whirlpool method" is removed by placing a layer of medium over the cornea (added to the inside wall of the chamber). Spray a gentle stream of medium through the medium layer, directing it towards the residual test article. If after several tries the test article cannot be removed, document this in the study notebook, and proceed to the next step.

j. Once each cornea is completely rinsed of test article, replace the glass window and window-locking ring. Continue rinsing as stated previously for the "closed chamber method" (see Section 6.5.1, step e).

k. Perform a post-treatment opacity reading for each cornea and record the results. Observe each cornea visually and, if applicable, record pertinent observations (e.g., dissimilar opacity patterns, tissue peeling or residual test article).

l. Incubate the holders in a vertical (anterior chamber facing forward) position at 32 ± 1°C for 120 ± 10 minutes. If other post-exposure incubation times are used, justification should be provided.

m. Record a post-incubation opacity reading for each cornea, which will be used to calculate the final corneal opacity value. Observe each cornea visually and record pertinent observations in the study notebook. Special attention is taken to observe dissimilar opacity patterns, tissue peeling or residual test substance, etc.

6.5.3 Solid and liquid surfactant test substances

Surfactant test substances are administered following one of the previously described procedures, with one exception: Surfactant test substances are tested on the cornea as a 10% (w/v) solution or suspension prepared in an appropriate solvent/vehicle (e.g., sterile deionized water).

6.5.4 Solid nonsurfactant test substances

Solid nonsurfactant test substances are administered following one of the previously described procedures, with a few exceptions, which are noted below:

- Solid test substances are tested on the cornea as a 20% (w/v) solution or suspension prepared in an appropriate solvent/vehicle (e.g., sterile deionized water).
- Solid test substances are incubated at 32 ± 1°C for 240 ± 10 minutes.
- There is no post-treatment incubation period. Thus, immediately following the rinsing process, both chambers are refilled (posterior chamber first) with fresh complete MEM,

and the post-treatment opacity readings are taken. During the post-treatment opacity reading, visual observations are performed for each cornea and, if necessary, are recorded in the workbook. Special attention is taken to observe dissimilar opacity patterns, tissue peeling or residual test article, etc. Immediately following these opacity readings and visual observations, the permeability experiment is performed.

6.6 Application of Sodium Fluorescein

Following the final opacity measurement, permeability of the cornea to Na-fluorescein is evaluated. The Na-fluorescein solution is applied to the cornea by one of two methods, depending on the nature of the test substance:

Liquid and surfactant test substances and surfactant preparations:

a. Remove the medium from both chambers (anterior chamber first).

b. Fill the posterior chamber with fresh complete MEM, and add 1 mL of a 4 mg/mL Na-fluorescein solution to the anterior chamber using a micropipettor.

c. Reseal the dosing holes in the top of both chambers with the chamber plugs.

Solid nonsurfactant test substances:

a. Remove the medium from the anterior chamber only and replace with 1 mL of a 5 mg/mL Na-fluorescein solution.

b. Reseal the dosing holes in the top of both chambers with the chamber plugs.

6.7 Permeability Determinations

a. After adding the Na-fluorescein to the anterior chamber and sealing the chambers, rotate the holders into a horizontal position with the anterior chamber facing up. Tilt the holders slightly, if necessary, to achieve a uniform application of the Na-fluorescein over the entire cornea. Incubate the holders in a horizontal position for 90 ± 5 minutes at 32 ± 1°C.

b. After the 90-minute incubation period, remove the medium in the posterior chamber of each holder and place into sample tubes prelabeled according to holder number. It is important to remove most of the medium from the posterior chamber and mix it in the tube so that a representative sample can be obtained for the OD_{490} determination.

c. After completing the Na-fluorescein penetration steps, the corneas should be fixed in an appropriate fixative (e.g., 10% neutral buffered formalin) at room temperature for at least 24 hours, so that the tissues are available if histology is necessary or requested at a later time. It is important that the corneas not be allowed to dry between transfer from the holders and fixation (submersion in the fixative).

d. If using a microplate reader to measure optical density, transfer 360 µL of the medium from each sample tube into its designated well on a 96-well plate. The standard plate map provides two wells for each cornea. The first well receives an undiluted sample from each cornea tested. When all of the media samples have been transferred onto the plate, measure and record their OD_{490}. Any OD_{490} value (of a control or test substance sample) that is 1.500 or greater must be diluted to bring the OD_{490} into the acceptable range. A dilution of 1:5 is generally sufficient but higher dilutions may be required. Prepare the dilution from the original sample of medium and transfer 360 µL into the second well designated for that cornea. Reread the plate and record the data from both

the undiluted and diluted OD_{490} values. Use the values from this second reading in all calculations. The OD_{490} values of less than 1.500 will be used in the permeability calculation.

Note: The linear range of absorbance of different microplate readers can vary. Thus, each laboratory must determine the upper limit of absorbance (in the linear range) for the microplate reader used in its facility.

e. If using a UV/VIS spectrophotometer to measure optical density, adjust the spectrophotometer to read at OD_{490}, and zero the spectrophotometer on a sample of complete MEM. Prior to reading samples from the BCOP assay, prepare and read two quality control samples of Na-fluorescein solution to ensure the Na-fluorescein calibration curve (see note below) conducted for the spectrophotometer is still acceptable. If the average of the quality control samples does not fall within the accepted range of the Na-fluorescein calibration curve, then prepare a Na-fluorescein calibration curve prior to running samples from the BCOP assay. If the average of the quality control samples falls within the accepted range of the calibration curve, then proceed to read samples from the BCOP assay. Transfer an aliquot of the mixed medium from the posterior chamber of the BCOP holder into a cuvette, then take and record an absorbance reading using the spectrophotometer. Any solutions giving an OD_{490} beyond the linear range of the spectrophotometer must be diluted in complete MEM, and another reading taken, repeating these steps until the OD_{490} is within the linear range of the spectrophotometer. Repeat these procedures for each sample from the BCOP assay, rinsing the cuvette(s) thoroughly between each sample, until all samples have been read and results recorded.

Note: If conducting this assay for the first time, a calibration curve for the spectrophotometer must be performed, using a series of dilutions of Na-fluorescein solution in complete MEM. A calibration curve should be prepared and used to determine the linear range of the spectrophotometer and thus determine the upper limit of absorbance.

6.8 Histopathology

A histopathological evaluation of the corneal tissue might be useful when the standard BCOP endpoints (i.e., corneal opacity and permeability) produce borderline results. A standardized scoring scheme using the formal language of pathology to describe any effects should be used.

6.9 Maintenance of the Corneal Holders

Following completion of the assay, clean the disassembled parts of each holder as follows:

a. Soak the posterior and anterior chambers in a solution of warm tap water and a dime-size or greater amount of Liquinox (or equivalent).

b. Soak the chamber plugs, O-rings, and handle screws in 70% ethanol. Rinse the chamber plugs, O-rings, and handle screws thoroughly in hot tap water, and air dry prior to reassembling the chambers.

c. Clean the interior and exterior surfaces of each pre-soaked posterior and anterior chamber by using a scrubbing sponge. Rinse each posterior and anterior chamber thoroughly in warm tap water and air dry prior to reassembling the chambers.

d. Match up each numbered posterior chamber with its corresponding anterior chamber; insert an O-ring into the appropriate place; attach a chamber handle screw to the anterior chamber; and finally insert the chamber screws into the anterior chamber.

7.0 Evaluation of Test Results

Results from the two test method endpoints, opacity and permeability, should be combined in an empirically derived formula that generates an *in vitro* irritancy score for each test substance.

7.1 Opacity

a. Calculate the change in opacity for each individual cornea (including the negative control) by subtracting the initial opacity reading from the final post-treatment opacity reading. Then calculate the average change in opacity for the negative control corneas.

b. Calculate a corrected opacity value for each treated cornea, positive control, and solvent/vehicle control (if applicable) by subtracting the average change in opacity of the negative control corneas from the change in opacity of each treated, positive control, or solvent/vehicle control cornea.

c. Calculate the mean opacity value of each treatment group by averaging the corrected opacity values of the treated corneas for each treatment group.

7.2 Permeability

Microplate Reader Method

a. Calculate the mean OD_{490} for the blank wells (plate blanks). Subtract the mean blank OD_{490} from the raw OD_{490} of each well (blank corrected OD_{490}).

b. If a dilution has been performed, correct the OD_{490} for the plate blank before the dilution factor is applied to the reading. Multiply each blank corrected OD_{490} by the dilution factor (e.g., a factor of 5 for a 1:5 dilution).

c. Calculate the final corrected OD_{490} value for each cornea by subtracting the mean OD_{490} value for the negative control corneas from the OD_{490} value of each treated cornea.

Final Corrected OD_{490} = (raw OD_{490} – mean blank OD_{490}) -mean blank corrected negative control OD_{490}

d. Calculate the mean OD_{490} value for each treatment group by averaging the final corrected OD_{490} values of the treated corneas for a particular treatment group.

UV/VIS Spectrophotometer Method

a. Calculate the corrected OD_{490} value of each treated, positive control, or solvent/vehicle control cornea by subtracting the average value of the negative control corneas from the original OD_{490} value for each cornea.

Final Corrected OD_{490} = raw OD_{490} -mean blank corrected negative control OD_{490}

b. Calculate the mean OD_{490} value for each treatment group by averaging the final corrected OD_{490} values of the treated corneas for a particular treatment group.

7.3 *In Vitro* Irritancy Score

Use the mean opacity and mean permeability values (OD_{490}) for each treatment group to calculate an *in vitro* score for each treatment group:

In Vitro Irritancy Score = mean opacity value + (15 x mean OD_{490} value)

Additionally, the opacity and permeability values should be evaluated independently to determine whether a test substance induced irritation through only one of the two endpoints.

8.0 Criteria for an Acceptable Test

A test is acceptable if the positive control gives an *in vitro* irritancy score that falls within two SDs of the current historical mean, which is to be updated at least every three months. In the BCOP, 100% ethanol induces a moderate to severe response (*in vitro* score = 39.9 - 65.4 at IIVS [n = 632]; mean = 52.7, standard deviation [SD] = 6.4), while 20% (w/v) imidazole induces a severe response (*in vitro* score = 69.7 - 136.2 at IIVS [n=125]; mean = 103, SD = 16.6). The negative or solvent/vehicle control responses should result in opacity and permeability values that are less than the established upper limits for background opacity and permeability values for bovine corneas treated with the respective negative or solvent/vehicle control.

9.0 Data Interpretation

The following classification system was established by Sina et al. (1995) based on studies with pharmaceutical intermediates exposed for 10 minutes (liquids) or 4 hours (solids).

In Vitro Score: 55.1 and above = severe irritant

While this classification system provides a good initial guide to interpretation of these *in vitro* data, these specific ranges may not be applicable to all classes of substances. For example, the Sina et al. (1995) scoring scale is not appropriate for anionic and nonionic surfactants since they produce appreciable permeability while inducing little direct opacity.

For these and other substances that produce significant permeability with minimal opacity, it is recommended that permeability values > 0.600 be considered severe. Benchmark substances are recommended for assaying the responses of test substances of different product or chemical classes. Histological evaluation of the corneas may be instrumental in identifying additional changes (e.g., peroxide-induced stromal damage).

10.0 Study Report

The test report should include the following information, if relevant to the conduct of the study:

Test and Control Substances

- Chemical name(s) such as the structural name used by the Chemical Abstracts Service (CAS), followed by other names, if known
- The CAS Registry Number (RN), if known
- Purity and composition of the substance or preparation (in percentage[s] by weight), to the extent this information is available
- Physicochemical properties such as physical state, volatility, pH, stability, chemical class, water solubility relevant to the conduct of the study
- Treatment of the test/control substances prior to testing, if applicable (e.g., warming, grinding)
- Stability, if known

Information Concerning the Sponsor and the Test Facility

- Name and address of the sponsor, test facility, and study director
- Identification of the source of the eyes (i.e., the facility from which they were collected)

- Storage and transport conditions of eyes (e.g., date and time of eye collection, time interval prior to initiating testing, transport media and temperature conditions, any antibiotics used)
- If available, specific characteristics of the animals from which the eyes were collected (e.g., age, sex, strain, weight of the donor animal)

Justification of the Test Method and Protocol Used

Test Method Integrity

- The procedure used to ensure the integrity (i.e., accuracy and reliability) of the test method over time (e.g., periodic testing of proficiency substances, use of historical negative and positive control data)

Criteria for an Acceptable Test

- Acceptable concurrent positive and negative control ranges based on historical data
- If applicable, acceptable concurrent benchmark control ranges based on historical data

Test Conditions

- Description of test system used
- Type of corneal holder used
- Calibration information for devices used for measuring opacity and permeability (e.g., opacitometer and spectrophotometer)
- Information on the bovine corneas used, including statements regarding their quality
- Details of test procedure used
- Test substance concentration(s) used
- Description of any modifications of the test procedure
- Reference to historical data of the model (e.g., negative and positive controls, proficiency substances, benchmark substances)
- Description of evaluation criteria used

Results

- Tabulation of data from individual test samples (e.g., opacity and OD_{490} values and calculated *in vitro* irritancy score for the test substance and the positive, negative, and benchmark controls [if included], reported in tabular form, including data from replicate repeat experiments as appropriate, and means ± the standard deviation for each experiment)
- Description of other effects observed

Discussion of the Results

Conclusion

A Quality Assurance Statement for Good Laboratory Practice (GLP)-Compliant Studies

- This statement indicates all inspections made during the study, and the dates any results were reported to the study director. This statement also serves to confirm that the final report reflects the raw data.

If GLP-compliant studies are performed, then additional reporting requirements provided in the relevant guidelines (e.g., OECD 1998; EPA 2003b, 2003c; FDA 2003) should be followed.

Appendix B2

ICCVAM-Recommended Protocol for Future Studies Using the Cytosensor Microphysiometer (CM) Test Method

This page intentionally left blank

PREFACE

This proposed protocol for ocular toxicity is based primarily on information obtained in INVITTOX Protocol 102 derived from the standard operation procedure used in the Home Office UK/EEC Validation Study for Alternatives to the Draize Test. The information contained within INVITTOX 102 was modified based upon the COLIPA protocol (Brantom et al., 1997; Harbell et al., 1999). Future studies using the CM test method could include further characterization of the usefulness and limitations of the CM test method in a weight-of-evidence approach for regulatory decision-making. Users should be aware that the proposed test method protocol could be revised based on any additional optimization and/or validation studies that are conducted in the future. ICCVAM recommends that test method users consult the NICEATM-ICCVAM website (http://iccvam.niehs.nih.gov/) to ensure use of the most current test method protocol.

1.0 Purpose and Applicability

The purpose of this study is to compare the ocular toxicity of the test material as predicted using the CM method with historical rabbit Draize eye data. The CM method evaluates the potential ocular toxicity by measuring the test material induced reduction in the metabolic rate in treated cultures of L929 cells. Change in metabolic rate is measured indirectly as a function of changes in extracellular acidification rate. The dose that induces a 50% decrease in metabolic rate is the end point of the assay.

The focus of this protocol is on the use of the CM test method for the detection of ocular corrosives and severe irritants and substances not labeled as irritants as defined by the U.S. Environmental Protection Agency (EPA; EPA 2003a), the European Union (EU; EU 2001), and United Nations Globally Harmonized System (GHS) of Classification and Labelling of Chemicals (UN 2007). Mild/moderate ocular irritants have been tested using this protocol; however, the CM test method is not currently considered to be adequately validated for these classes of ocular irritancy as defined by EPA (2003a), EU (2001), and GHS (UN 2007).

2.0 Safety and Operating Precautions

All procedures with L929 cells should follow the institution's applicable regulations and procedures for handling human or animal substances, which include, but are not limited to, tissues and tissue fluids. Universal laboratory precautions are recommended, including the use of laboratory coats, eye protection, and gloves. If available, additional precautions required for specific study substances should be identified in the Material Safety Data Sheet for that substance.

3.0 Materials, Equipment, and Supplies

3.1 Equipment and Supplies

- Aspirator
- Balance
- Beakers, disposable
- Capsules, eight with L-929 cells grown to be <80% confluent at time of use (confluent monolayer could interfere with accurate CM readings) in DMEM. To prepare these, load 5-6 x 10^5 cells about 18 hr prior to use and incubate in complete DMEM with 1% calf serum under standard culture conditions.
- Cell culture equipment for preparation of cells
- Cytosensor System with eight sterilized chambers, set up in the injection loop mode - Molecular Devices Corporation, Menlo Park, California, USA

- Cytosoft and the following Cytosoft protocols for toxicity testing:
  - — Tox Maintenance (ii) Routine Tox 003 (4x2) (both supplied by MDC)
  - — A statistics program capable of MRD_{50}
- Pipettors, rack, etc., for preparation of dilutions
- Refrigerator
- Statistical program for calculation of MRD_{50}
- Tubes, 15 ml, for preparation of dilutions (4 dilutions per test sample).
- Tube racks
- Syringes, 4 x 5 ml and a 30 ml
- Water bath

3.2 Media and Reagents

- Assay Medium: DMEM complete with 1% Fetal Bovine Serum, 5.0 μg/ml gentamicin, 2.0 mM L-glutamine, and 1.0 mM sodium pyruvate.
- Growth Medium: Dulbecco's modified Eagle's medium (DMEM) (1mg/ml glucose) complete with 10% Fetal Bovine Serum, 2.0 mM L-glutamine, and 1.0 mM sodium pyruvate.
- Positive Control: Sodium lauryl sulfate (SLS) 10% in water (stock).
- Treatment medium: Serum-free, Sodium Bicarbonate-free, DMEM with 5.0 μg/ml gentamicin, 2.0 mM L-glutamine, and additional NaCl for consistent osmolarity (MDMEM). 11.1 ml of 4 M NaCl is required per liter.
- Trypsin, 0.05% in Ca^{+2} and Mg^{+2}-free Hank's Balanced Salt Solution.

4.0 Test Substance Preparation

The test article will be dissolved in MDMEM. It is essential that the test material be in a single-phase solution in the highest dose used (300 mg/mL) to prepare the subsequent dilutions. If the substance cannot form a single phase solution/suspension at a concentration of 33.3 mg/mL, the test sample cannot be tested by the CM using standard techniques.

The stability of the test article under the actual experimental conditions will not be determined by the testing laboratory.

5.0 Controls

5.1 Negative Control

The baseline acidification rate will serve as the internal negative control for each cell culture. Baseline rates will fall between 50 and 150 microvolts/sec after a stabilization period of at least 15 minutes. Replace the cell-containing insert in a chamber that fails to achieve these ranges.

5.2 Solvent/Vehicle Control

Untreated controls are recommended when solvents/vehicles other than 0.9% sodium chloride or distilled water are used to dissolve test substances, in order to demonstrate that the solvent/vehicle is not interfering with the test system.

5.3 Positive Control

When the 8-channel Cytosensor is used, a positive control assay will be performed with each definitive trial of the assay. When the 4-channel machine is used, a concurrent positive control trial will be performed with at least one of the definitive trials for each test material. The positive control substance is SLS prepared from a 10% stock in water.

5.4 Benchmark Substances (if appropriate)

Benchmark substances are useful for evaluating the ocular irritancy potential of unknown chemicals of a specific chemical or product class, or for evaluating the relative irritancy potential of an ocular irritant within a specific range of irritant responses. Appropriate benchmark substances should have the following properties:

- A consistent and reliable source(s)
- Structural and functional similarity to the class of the substance being tested
- Known physical/chemical characteristics
- Supporting data on known effects in the *in vivo* rabbit eye test
- Known potency in the range of the desired response

6.0 Experimental Design

6.1 Filling the Workstations with Medium

Put 8 x 50 ml tubes, each having at least 20 ml of MDMEM on the Cytosensor and fill the injection loops with MDMEM, using a 30 ml syringe. Using the "Front Panel" controls, set the flow rate to 90-100% to fill the lines, and then set the flow rate back to idle (5%).

6.2 Checking out the Equipment

Empty Sterilant from the sensor chambers, wash them by repeated filling with, and aspiration of, distilled water, and then add about 2 ml of low-buffer DMEM to each chamber. Put them on the Cytosensor. Set flow rate to High (90-100% of max) and clear obvious bubbles. Run Cytosoft default protocol ("New") to see that system sets up and the background rate in the absence of cells settles within 10 minutes to between +5 and -5 microvolts/sec. This gives the opportunity to attend to any equipment problems before starting to use cells.

6.3 Checking out the Cells

Exit "New" protocol and set flow rate to Normal (approx. 50%) using "Front Panel" controls. To at least 8 cell-containing cell capsules in a culture tray containing Low-Buffered DMEM, add spacers and inserts as described in the Manual. Move the tray to the Cytosensor and use forceps to transfer the completed capsules to the sensor chambers, lifting the gantries and raising the plungers one set at a time. When all the capsules are in place, set the flow rate to High and clear obvious bubbles again.

6.4 Cell Culture Maintenance and Preparation of the Capsule Cups

Stock cultures of L929 cells will be maintained and passaged in Growth Medium and incubated at $37 \pm 1^{o}C$ and $5 \pm 1\%$ CO_2 in air. L929 cells will be seeded onto capsule cups at approximately 6.0×10^5 cells per capsule cup in Seeding Medium as described below.

Flasks of L929 cells to be passaged or seeded are selected at or near confluency. The size of flasks used will depend on the number of cells needed. The Growth Medium is decanted and the cell sheet washed twice with approximately 10 mL of PBS for each $75cm^2$ of growth surface. The cells are

trypsinized with approximately 3 mL of 0.05% trypsin (for each 75cm^2 of growth surface) for 15 to 30 seconds. The trypsin solution is aspirated and the cells are incubated at room temperature for approximately 2 to 5 minutes, until the cells begin to round. The cells are dislodged by tapping the flask, which contains approximately 5mL of Seeding Medium for each 75cm^2 of growth surface. The cells are triturated using a pipet in order to break up clumps and are transferred by pipet to a conical centrifuge tube. If more than one flask is used, the contents of each are pooled. Cell counts are performed as required. The L929 cells will be seeded with approximately 6.0 x 10^5 cells per each capsule cup (0.5 mL of a 1.2 x 10^6 cell suspension) with 1.5 mL of Seeding Medium added to each outside well. The plate will be incubated at 37 ± 1°C and 5 ± 1% CO_2 in air for 16 to 32 hours. Prior to the start of the assay, the medium in capsule cups will be switched to Low-Buffered DMEM and a spacer will be added to each capsule cup and gently tapped down to the bottom. The cell capsules will be placed into the sensor chambers and exposed to Low-Buffered DMEM at 37 ± 1^{o}C.

For routine passaging, the stock cultures are trypsinized as described above, but are dislodged and resuspended using warm (approximately 37^{o}C) Growth Medium, seeded into a culture flask(s), and returned to the humidified incubator maintained at 37 ± 1^{o}C and 5 ± 1% CO_2 in air.

6.5 Dose Range Finding Assay

A dose range finding assay will be performed to establish an appropriate test article dose range for the definitive CM assay. Dosing solutions will be prepared by serial three-fold dilutions (producing the same concentrations suggested in the following table) in sterile, Low-Buffered DMEM that has been allowed to equilibrate to room temperature.

IMPORTANT: Do not attempt to use preparations that separate into more than one phase in the Cytosensor. Similarly, do not attempt to use such preparations to make dilutions. At the discretion of the Study Director, a suspension that maintains a single phase may be assayed and used to prepare further dilutions.

If the sample does not go into a single phase with the medium at 10.0 mg/mL (maintaining a ratio of 100 mg/10 mL), prepare dilutions 2 or 3 as required. If a single-phase test article/medium mixture is not achieved, the Study Director and Sponsor are to be consulted.

Dilution #	Concentration
1	10 mg/mL
2	3.33 mg/mL
3	1.11 mg/mL
4	0.370 mg/mL
5	0.123 mg/mL
6	0.0412 mg/mL
7	0.0137 mg/mL

The test article will be evaluated by exposure to L929 cells contained in sensor chambers. After the baseline data points have been taken, the exposure cycle will begin with the lowest test article concentration. From these baseline data points, the spreadsheet will compute the mean baseline value used in the MRD_{50} calculation. Each exposure cycle will take 20 minutes.

The maximum solvent concentration (other than Low-Buffered DMEM) will be 10% unless otherwise specified.

There will be three phases in the exposure cycle, with the following parameters selected within the CM software (Cytosoft): First, a test article concentration will be introduced into the sensor chamber for 13 minutes and 30 seconds. The nominal rate of flow will be 100 µL per minute for the first minute, and 20 µL per minute for the next 12 minutes and 30 seconds. The second phase will be the washout phase, which will be 6 minutes at a nominal rate of 100 µL per minute. The test article will be washed out of the sensor chamber during this phase. Finally, the third phase will be the measurement of the acidification rate. For 25 seconds, there will be no flow and the rate of pH change will be measured.

The exposure cycle will repeat with increasing test article concentrations until either the highest test article concentration is reached or until the MRD_{50} value has been surpassed. Each test article concentration will be tested on a single set of cells. Positive control materials and solvent controls (for solvents other than Low-Buffered DMEM) will be tested in the same fashion. If possible, an MRD_{50} value will be calculated from the dose range finding assay.

The test article doses for the definitive assay will be chosen so that generally seven doses (spaced as three-fold dilutions) will be available for the determination of the MRD_{50}. Generally, three concentrations will be chosen to result in expected survivals lower than 50%, one concentration will be chosen to result in an expected survival of approximately 50%, and three or more concentrations will be chosen to result in expected survivals greater than 50%. If a test article fails to cause 50% toxicity in the dose range finding CM assay, the maximum dose will generally be 270 mg/mL, or less based on its solubility/workability.

6.6 Definitive Assay

The definitive assay will be performed in the same manner as the dose range finding assay, with the exception that if the MRD_{50} value from the dose range finding assay is >10 mg/mL, higher doses of test article will be prepared and tested in the definitive assay. At least seven doses, spaced at three-fold dilution intervals, up to a maximum of 270 mg/mL will be prepared. The determination of the final MRD_{50} will be based upon the results of at least two definitive assays and will generally also include the results of the dose range finding assay, if an MRD_{50} could be determined. The results from additional definitive assays may also be incorporated into the calculation of the final MRD_{50}.

7.0 Evaluation of Test Results

The acidification rates that occur after exposure to each test article concentration are calculated by the CM software (Cytosoft) and compared to the mean acidification rate (base acidification rate) of the same cells prior to exposure to a test material. The percent of control acidification rate will be determined by comparing the dose response acidification rate to the base acidification rate. The dose response curve will be plotted with the percent of control acidification rates on the ordinate and the test article concentration on the abscissa. The concentration of the test material that results in a fifty percent reduction in acidification is interpolated from the curve and referred to as the MRD_{50}. These calculations can be performed using the Excel spreadsheet program provided for this study.

8.0 Criteria for an Acceptable Test

Assay acceptance criteria are normally based on the performance of the positive control. The CM assay would be accepted if the positive control MRD_{50} fell within 2 standard deviations of the historical range. The acceptable range for SLS will be provided by the lead laboratory. The positive control assay will not be performed with each trial on the 4-channel machine. Therefore, acceptance of those trials, lacking a positive control, will be based on judgment of the study director.

9.0 Data Interpretation

Interpretation of MRD_{50} values is done according to the decision criteria provided in Background Review Document: Existing Methods for Eye Irritation Testing: Silicon Microphysiometer and CM (ECVAM 2008), as follows:

For the EU system (EU 2001) the proposed PM is

	MRD_{50}
R41	<2 mg/mL
R36	<10 mg/mL; >2 mg/mL
Not classified	>10 mg/mL

For the GHS system (UN 2007) the proposed PM is

	MRD_{50}
1	<2 mg/mL
2A or 2B	<10 mg/mL; >2 mg/mL
No Label	>10 mg/mL

For the EPA system (EPA 2003a) the proposed PM is

	MRD_{50}
1	<2 mg/mL
III	<80 mg/mL; >2 mg/mL
Not classified	>80 mg/mL

10.0 Study Report

The test report should include the following information, if relevant to the conduct of the study:

Test and Control Substances

- Chemical name(s) such as the structural name used by the Chemical Abstracts Service (CAS), followed by other names, if known
- The CAS Registry Number (RN), if known
- Purity and composition of the substance or preparation (in percentage(s) by weight), to the extent this information is available
- Physicochemical properties such as physical state, volatility, pH, stability, chemical class, water solubility relevant to the conduct of the study
- Treatment of the test/control substances prior to testing, if applicable (e.g., warming, grinding)
- Stability, if known

Information Concerning the Sponsor and the Test Facility

- Name and address of the sponsor

- Name and address of the test facility
- Name and address of the Study Director

Justification of the Test Method and Protocol Used

Test Method Integrity

- The procedure used to ensure the integrity (i.e., accuracy and reliability) of the test method over time (e.g., periodic testing of proficiency substances, use of historical negative and positive control data)

Criteria for an Acceptable Test

- Acceptable concurrent negative control ranges based on historical data
- Acceptable concurrent positive control ranges based on historical data
- If applicable, acceptable concurrent benchmark control ranges based on historical data

Test Conditions

- Description of test system used
- Calibration information for measuring device used
- Details of test procedure used
- Test concentration(s) used
- Description of any modifications of the test procedure
- Reference to historical data of the model (e.g., negative and positive controls, proficiency substances, benchmark substances)
- Description of evaluation criteria used

Results

- Tabulation of data from individual test samples

Description of Other Effects Observed

Discussion of the Results

Conclusion

A Quality Assurance Statement for Good Laboratory Practice (GLP)-Compliant Studies

- This statement indicates all inspections made during the study, and the dates any results were reported to the Study Director. This statement also serves to confirm that the final report reflects the raw data.

If GLP-compliant studies are performed, then additional reporting requirements provided in the relevant guidelines (e.g., OECD 1998; EPA 2003b, 2003c; FDA 2003) should be followed.

Appendix B3

ICCVAM-Recommended Protocol for Future Studies Using the Hen's Egg Test – Chorioallantoic Membrane (HET-CAM) Test Method

ICCVAM recommends this HET-CAM test method protocol for nonregulatory, validation, or optimization studies to facilitate collection of consistent data and expand the available database. Exceptions and/or changes to the test method protocol should be accompanied by a scientific rationale.

This page intentionally left blank

PREFACE

The protocol was adapted from the protocol previously described by Spielmann and Liebsch (INVITTOX 1992). Examples of the use of this protocol can be found in Luepke (1985), Balls et al. (1995), Gilleron et al. (1996, 1997), and Spielmann et al. (1996). Future studies using the HET-CAM test method could include further characterization of the usefulness and limitations of the HET-CAM test method in a weight-of-evidence approach for regulatory decision-making. Users should be aware that the proposed test method protocol could be revised based on any additional optimization and/or validation studies that are conducted in the future. ICCVAM recommends that test method users consult the NICEATM-ICCVAM website (http://iccvam.niehs.nih.gov/) to ensure use of the most current test method protocol.

1.0 Purpose and Applicability

The purpose of this protocol is to describe the components and procedures used to evaluate the potential ocular irritancy of a test substance as measured by its ability to induce toxicity in the chorioallantoic membrane of a chicken. Effects are measured by the onset of (1) hemorrhage; (2) coagulation; and (3) vessel lysis. These assessments are considered individually and then combined to derive a score, which is used to classify the irritancy level of the test substance.

The focus of this protocol is on the use of the HET-CAM test method for the detection of ocular corrosives and severe irritants, as defined by the U.S. Environmental Protection Agency (EPA 2003a), European Union (EU; EU 2001), and United Nations Globally Harmonized System (GHS) of Classification and Labelling of Chemicals (UN 2007). However, the HET-CAM test method is not currently considered to be adequately validated for classification of ocular irritancy as defined by EPA (2003a), EU (2001), and GHS (UN 2007).

This HET-CAM test method protocol has been modified from a generic description of the Irritation Score (IS) analysis method to include a more detailed IS(A) analysis method to be used for prospective studies. However, a description of the IS(B) analysis method, which was described in 2006 (ICCVAM 2006) is included for retrospective analyses, where IS(B) analysis method data could be converted to fixed time points similar to those used for the IS(A) analysis method described in **Section 7.0**.

ICCVAM recommends this HET-CAM test method protocol for nonregulatory, validation, or optimization studies to facilitate collection of consistent data and expand the available database. Exceptions and/or changes to the test method protocol should be accompanied by a scientific rationale.

2.0 Safety and Operating Precautions

All procedures with chicken eggs should follow the institution's applicable regulations and procedures for handling of human or animal materials, which include, but are not limited to, tissues and tissue fluids. Universal laboratory precautions are recommended, including the use of laboratory coats, eye protection, and gloves. If available, additional precautions required for specific study substances should be identified in the Material Safety Data Sheet for that substance.

3.0 Materials, Equipment, and Supplies

3.1 Source of Chicken Eggs

Fertile White Leghorn chicken eggs should be obtained from commercial sources. Fresh (not older than seven days), fertile, clean eggs weighing between 50 and 60 grams should be used. Eggs should

be candled prior to use and nonviable or defective eggs should be discarded. Excessively misshapen eggs or eggs with cracked or thin shells should not be used. Transport of eggs should occur under conditions that will not affect embryo viability or development.

3.2 Equipment and Supplies

- Candling light
- Deionized/Distilled Water
- Dentist's rotating saw blade
- Incubator with an automatic rotating device
- Micropipette(s) and disposable tips appropriate for recommended volumes
- Mortar and pestle (or comparable grinding tools for test substances)
- Stop clock or electronic chronometer
- Standard general biological laboratory equipment and supplies (e.g., microcentrifuge tubes for measurement of substance volume), as needed
- Tapered forceps
- Volumetric flasks

3.3 Solutions

The manufacturer's recommendations should be followed with regard to storage temperature and shelf life of stock solutions. Solutions should be prepared volumetrically.

- 0.9% (w/v) sodium chloride (NaCl) in deionized/distilled water
- 1% (w/v) sodium dodecyl sulfate (SDS) in deionized/distilled water
- 0.1 N sodium hydroxide (NaOH) in deionized/distilled water

4.0 Test Substance Preparation

All test substances should be evaluated undiluted unless dilution is justified. If dilution is justified, then 0.9% NaCl or olive oil should be used as the diluent, depending on substance solubility. Use of a different solvent should be justified. Dilutions should be prepared on the same day as the test.

Paste, particulate, or granular test substances or formulations should be evaluated without dilution. Solid test substances should be ground to a fine dust to obtain a volume of 0.3 mL after gentle compaction of the particulates in a measuring container (e.g., microcentrifuge tube).

5.0 Controls

5.1 Negative Control

A 0.9% NaCl negative control should be included in each experiment in order to provide a baseline for the assay endpoints and to ensure that the assay conditions do not inappropriately result in an irritant response.

5.2 Solvent Control (if appropriate)

If the test substance is diluted in olive oil, then this solvent should be included as a control substance in order to provide a baseline for the assay endpoints and to ensure that the assay conditions do not inappropriately result in an irritant response. If a solvent other than 0.9% NaCl or olive oil is used, than both the solvent and 0.9% NaCl should be included as controls to ensure that the alternative solvent does not result in an irritant response.

5.3 Positive Control

A known ocular irritant should be included in each experiment to verify that an appropriate response is induced. If the HET-CAM assay is being used only to identify corrosive or severe irritants, then the positive control should be a substance (e.g., 1% SDS, NaOH) that induces a severe response *in vivo* as well as in HET-CAM. However, to ensure that variability in the positive control response across time can be assessed, the magnitude of the severe response should not be excessive. The selection of positive control test substances should be based on the availability of high quality *in vivo* data.

5.4 Benchmark Control (if appropriate)

Benchmark controls may be useful in demonstrating that the test method is functioning properly for detecting the ocular irritancy potential of chemicals of a specific chemical class or a specific range of responses, or for evaluating the relative irritancy potential of an ocular irritant. Appropriate benchmark controls should have the following properties:

- A consistent and reliable source(s)
- Structural and functional similarity to the class of the substance being tested
- Known physical/chemical characteristics
- Supporting data on known effects in the *in vivo* rabbit eye test
- Known potency in the range of the desired response

6.0 Experimental Design

6.1 Treatment Groups

Use at least three eggs per group (negative and positive controls, test substance, and, if included, benchmark and solvent controls). To the extent possible, eggs from the same hen should be randomized among treatment groups.

6.2 CAM Preparation

a. Select fresh (not older than 7 days), clean, fertile 50-60 g White Leghorn chicken eggs. Candle the eggs and discard any eggs that are nonviable or defective. Excessively misshapen eggs or eggs with cracked or thin shells should not be used. Shaking, unnecessary tilting, knocking, and all other mechanical irritation of the eggs should be avoided when preparing.

b. Place eggs in an incubator with a rotating tray. Incubate eggs at 38.3 ± 0.2°C and 58 ± 2% relative humidity when incubating in a still-air incubator or at 37.8 ± 0.3ºC and 58 ± 2% relative humidity when incubating in a forced-air incubator. Hand rotate eggs five times per day until day 8.

c. Candle the eggs on incubation day 8 and remove any nonviable or defective eggs. Eggs are returned to the incubator (without hand rotation) with the large end of the eggs upwards for an additional day.

d. Remove eggs from the incubator on day 9 for use in the assay. Candle eggs and discard any nonviable or defective eggs.

e. Mark the air cell of the egg. Cut the section marked as the air cell with a rotating dentist saw blade and then pare it off. Care should be taken when removing the eggshell to ensure that the inner membrane is not injured.

f. Moisten the inner membrane with 0.9% NaCl. A disposable glass pipette can be used to apply the solution. Place the egg into the incubator for a maximum of 30 minutes.

g. Remove the egg from the incubator, prior to its use in the assay, and decant the 0.9% NaCl solution. Carefully remove the inner membrane with forceps, ensuring that the inner membrane is not injured.

6.3 Treatment of Eggs with Test Substances

Depending on the physical form of the test substance, the following form-specific application protocols should be followed.

6.3.1 Liquid or diluted test substances or formulations

Apply 0.3 mL of liquid substances or diluted substances directly onto the CAM surface.

6.3.2 Solid, particulate, or granular test substances or formulations

Apply 0.3 mL of solid, particulate, or granular substances (which have been ground to a fine dust) directly onto the CAM, ensuring that at least 50 % of the CAM surface area is covered. In cases where the total weight of the test substance at this volume is greater that 0.3 g, 0.3 g of the solid, particulate, or granular test substance should be used. In either case, the weight of the test substance should be recorded.

6.3.3 Paste test substances or formulations

Apply 0.3 mL of paste substances or formulations directly onto the CAM, ensuring that at least 50% of the CAM surface area is covered. In cases where the total weight of the test substance at this volume is greater that 0.3 g, 0.3 g of the paste test substance should be used. In either case, the weight of the test substance should be recorded.

6.4 Observations

Observe the reactions on the CAM over a period of 300 seconds. The time for the appearance of each of the noted endpoints should be monitored and recorded, in seconds. Endpoints that should be observed are:

- Hemorrhage (bleeding from the vessels)
- Vascular lysis (blood vessel disintegration)
- Coagulation (intra- and extra-vascular protein denaturation)

Hemorrhage time = observed start (in seconds) of hemorrhage reactions on CAM

Lysis time = observed start (in seconds) of vessel lysis on CAM

Coagulation time = observed start (in seconds) of coagulation formation on CAM

Collection of additional information and data may be useful in further analyses and conducting retrospective studies. To maximize the likelihood of obtaining reproducible results, reference photographs for all endpoints should be available.

7.0 Evaluation of Test Results

The ICCVAM-recommended HET-CAM protocol for prospective studies is the IS(A) analysis method, which is based on development of each of the three HET-CAM endpoints at fixed time intervals of 0.5, 2, and 5 minutes (Luepke 1985).

The numerical time-dependent scores for lysis, hemorrhage, and coagulation (**Table 7-1**) are summed to give a single numerical value indicating the irritation potential of the test substance on a scale with a maximum value of 21.

Table 7-1 Scoring Scheme for Irritation Testing with the HET-CAM Test Method

Effect	Score		
	0.5 min	**2 min**	**5 min**
Lysis	5	3	1
Hemorrhage	7	5	3
Coagulation	9	7	5

For retrospective analyses, data from the HET-CAM test method protocol using the IS(B) analysis method (ICCVAM 2006) could be converted to fixed time points similar to those used for the IS(A) analysis method.

8.0 Criteria for an Acceptable Test

A test is considered acceptable if the negative and positive controls each induce a response that falls within the classification of nonirritating and severely irritating, respectively. Historical control studies indicate that using 0.9% NaCl, as a negative control, the IS value was 0.0. Historical control studies indicate that using 1% SDS and 0.1 N NaOH, as positive controls, the IS values ranged between 10 and 19, respectively.

9.0 Data Interpretation

When using the IS analysis method, the severe irritancy classification for a test substance is assigned when the value is greater than nine.

10.0 Study Report

Information and data that should be included in study reports for the HET-CAM test method include, but are not limited to:

Test and Control Substances

- Chemical name(s) such as the structural name used by the Chemical Abstracts Service (CAS), followed by other names, if known
- The CAS Registry Number (RN), if known
- Purity and composition of the substance or preparation (in percentage(s) by weight)
- Physicochemical properties such as physical state, volatility, pH, stability, chemical class, water solubility relevant to the conduct of the study
- Treatment of the test/control substances prior to testing, if applicable (e.g., warming, grinding)
- Stability, if known

Information Concerning the Sponsor and the Test Facility

- Name and address of the Sponsor
- Name and address of the test facility
- Name and address of the Study Director

Justification of the Test Method and Protocol Used

Test Method Integrity

- The procedure used to ensure the integrity (i.e., accuracy and reliability) of the test method over time (e.g., periodic testing of proficiency substances, use of historical negative and positive control data)

Criteria for an Acceptable Test

- Acceptable concurrent negative control ranges based on historical data
- Acceptable concurrent positive control ranges based on historical data
- If applicable, acceptable concurrent benchmark control ranges based on historical data

Test Conditions

- Experimental starting and completion dates
- Details of test procedure used
- Test concentration(s) used
- Description of any modifications of the test procedure
- Reference to historical data of the model (e.g., negative and positive controls, proficiency substances, benchmark substances)
- Description of evaluation criteria used

Results

- Tabulation of data from individual test samples (e.g., irritancy scores for the test substance and the various controls, including data from replicate repeat experiments as appropriate, and means and ± the standard deviation for each test)

Description of Other Effects Observed

Discussion of the Results

Conclusion

A Quality Assurance Statement for Good Laboratory Practice (GLP)-Compliant Studies

- This statement indicates all inspections made during the study, and the dates any results were reported to the Study Director. This statement also serves to confirm that the final report reflects the raw data.

If GLP-compliant studies are performed, then additional reporting requirements provided in the relevant guidelines (e.g., OECD 1998; EPA 2003b, 2003c; FDA 2003) should be followed.

Appendix B4

ICCVAM-Recommended Protocol for Future Studies Using the Isolated Chicken Eye (ICE) Test Method

This page intentionally left blank

PREFACE

This proposed protocol for measuring corneal damage was developed following a comprehensive test method evaluation process conducted by ICCVAM, which included an international independent scientific peer review of the validation status and scientific validity of the ICE (ICCVAM 2006a,b). It is based primarily on the current protocol used by Menk Prinsen, the original developer of the test method (Prinsen and Koeter 1993; INVITTOX 1994; Balls et al. 1995; Prinsen 1996; Chamberlain et al. 1997). Future studies using the ICE test method could include further characterization of the usefulness or limitations of the ICE in a weight-of-evidence approach for regulatory decision-making. Users should be aware that the proposed test method protocol could be revised based on any additional optimization and/or validation studies that are conducted in the future. ICCVAM recommends that test method users consult the NICEATM-ICCVAM website (http://iccvam.niehs.nih.gov/) to ensure use of the most current test method protocol.

1.0 Purpose and Applicability

The purpose of this protocol is to describe the procedures used to evaluate the potential ocular irritancy of a test substance as measured by its ability to induce toxicity in an enucleated chicken eye. Toxic effects are measured by (1) qualitative assessment of corneal opacity; (2) qualitative measurement of increased retention of fluorescein dye within the eye (permeability); (3) quantitative measurement of increased corneal thickness (swelling); and (4) qualitative evaluation of macroscopic morphological damage to the corneal surface. The opacity, swelling, and permeability assessments following exposure to a test article are assessed individually and then combined to derive an Eye Irritancy Classification.

The focus of this protocol is on the use of the ICE test method for the detection of ocular corrosives and severe irritants, as defined by the U.S. Environmental Protection Agency (EPA; EPA 2003a), European Union (EU; EU 2001), and United Nations Globally Harmonized System (GHS) of Classification and Labelling of Chemicals (UN 2007). Substances other than ocular corrosives and severe irritants (e.g., substances not labeled as irritants and mild/moderate ocular irritants) have been tested using this protocol; however, the ICE test method is not currently considered to be adequately validated for these classes of ocular irritancy as defined by EPA (2003a), EU (2001), and GHS (UN 2007).

2.0 Safety and Operating Precautions

All procedures with chicken eyes should follow the institution's applicable regulations and procedures for handling of human or animal materials, which include, but are not limited to, tissues and tissue fluids. Universal laboratory precautions are recommended, including the use of laboratory coats, eye protection, and gloves. If available, additional precautions required for specific study substances should be identified in the Material Safety Data Sheet for that substance.

3.0 Materials, Equipment, and Supplies

3.1 Source of Chicken Eyes

Spring chickens obtained from a local source (e.g., poultry abattoir), approximately 7 weeks old, male or female, with a weight range of 2.5–3.0 kg (breed not specified).

3.2 Equipment and Supplies

- Custom superfusion apparatus (that will accommodate the eye holders) with a water pump for temperature control
- Dissection equipment (e.g., scissors and forceps)
- Electronic balance
- Eye holders (custom stainless steel clamps)
- Micropipettor and pipette tips
- Mortar and pestle
- Physiological saline
- Slit-lamp microscope with an optical pachymeter equipped with centering lights
- Tissue paper
- Transportation chambers (humidified plastic boxes containing tissues moistened with isotonic saline or water)
- Volumetric flasks
- Peristaltic pump for the saline drip onto the eye

3.3 Solutions

The manufacturer's recommendations with regard to storage temperature and shelf life of stock solutions should be followed. Assay solutions should be prepared volumetrically.

- Fluorescein sodium BP, 2% w/v (also available commercially)
- Isotonic saline (i.e., 0.9% NaCl)
- 4% neutral buffered formaldehyde

4.0 Test Substance Preparation

4.1 Liquid Test Substances

Liquid test substances are typically tested undiluted, but may be diluted if deemed necessary (e.g., as part of the study design). The preferred solvents for diluted substances are either deionized/distilled water or physiological saline. However, alternative solvents may also be used under controlled conditions, but the appropriateness of solvents other than deionized/distilled water or physiological saline must be demonstrated.

4.2 Solid Test Substances

Prior to testing, solid, particulate or granular test substances should be ground as finely as possible in a mortar and pestle.

5.0 Controls

5.1 Negative Controls

A negative control (e.g. deionized/distilled water, isotonic saline, other assay medium) should be included in each experiment in order to detect non-specific changes in the test system, and to ensure that the assay conditions do not inappropriately result in an irritant response.

5.2 Solvent/Vehicle Controls

Solvent/vehicle controls are recommended when solvents/vehicles other than deionized/distilled water, saline, or other assay medium are used to dissolve test substances, in order to demonstrate that the solvent/vehicle is not interfering with the test system.

5.3 Positive Controls

A known ocular irritant is included as a concurrent positive control in each experiment to verify that an appropriate response is induced. As the ICE assay is being used to identify corrosive or severe irritants, the positive control should be a reference substance that induces a severe response in this test method. However, to ensure that variability in the positive control response across time can be assessed, the magnitude of the severe response should not be excessive. Sufficient *in vitro* data for the positive control should be generated such that a statistically defined acceptable range for the positive control can be calculated. If adequate historical ICE test method data are not available for a particular positive control, studies may need to be conducted to provide this information.

Examples of positive controls for liquid test substances are 10% acetic acid or 5% benzalkonium chloride, while examples of positive controls for solid test substances are sodium hydroxide or imidazole.

5.4 Benchmark Controls

Benchmark controls may be useful to demonstrate that the test method is functioning properly for detecting the ocular irritancy potential of chemicals of a specific chemical class or a specific range of responses, or for evaluating the relative irritancy potential of an ocular irritant. Appropriate benchmark controls should have the following properties:

- A consistent and reliable source(s) for the chemical
- Structural and functional similarity to the class of the substance being tested
- Known physical/chemical characteristics
- Supporting data on known effects in animal models
- Known potency in the range of the desired response

6.0 Experimental Design

6.1 Collection and Transport Conditions of Chicken Eyes

Heads of spring chickens should be obtained from a local source (e.g., poultry abattoir). Heads should be removed immediately after sedation of the animals by electric shock and incision of the neck for bleeding. Chicken heads may then be transported to the laboratory at ambient temperature in humidified plastic boxes (i.e., sealed with tissues moistened with isotonic saline) within two hours after they are humanely killed. Once at the laboratory, the eyes may be dissected from each chicken head.

6.2 Preparation of Eyes

a. Carefully remove the eyelids without damaging the cornea. Place a drop of fluorescein sodium BP 2% w/v onto the corneal surface for 10-20 seconds, and then immediately rinse the eye with 20 mL isotonic saline. Examine the fluorescein-treated cornea with a slit-lamp microscope to ensure that the cornea is undamaged (i.e., fluorescein retention and corneal opacity scores < 0.5).

b. If undamaged, further dissect the eye from the eye socket, taking care not to damage the corneal epithelium. When removing the eye from the orbit, a visible portion of the optic nerve should be left attached to the eye.

c. Once removed from the orbit, place the eye on an underpad and cut away the nictitating membrane and other connective tissue.

d. Mount the eyes in stainless steel clamps (one eye per clamp), with the cornea positioned vertically and then transfer each clamp to a chamber in the superfusion apparatus. The chambers of the superfusion apparatus should be temperature controlled at 32 ± 1.5°C with a water pump. Position the clamp in the superfusion apparatus such that the entire cornea is supplied with isotonic saline from a bent stainless steel tube at a rate of 0.10-0.15 mL/minute via a peristaltic pump.

e. After being placed in the superfusion apparatus, the eyes are again examined with a slit-lamp microscope to ensure that they have not been damaged during the dissection procedure. Corneal thickness should also be measured at this time at the corneal apex using the depth measuring device on the slit-lamp microscope. Eyes with (i), a fluorescein retention score of > 0.5; (ii) corneal opacity > 0.5; or, (iii), any additional signs of damage should be replaced. For eyes that are not rejected based on any of these criteria, individual eyes with a corneal thickness deviating more than 10% from the mean value for all eyes are to be rejected. Users should be aware that slit-lamp microscopes could yield different corneal thickness measurements if the slit-width setting is different. The slit-width should be set at 0.095 mm.

f. Once all eyes have been examined and approved, incubate eyes at 32 ± 1.5 °C for 45-60 minutes to equilibrate them to the test system prior to dosing.

6.3 Treatment Groups

Each treatment group and concurrent positive control consists of a minimum of three eyes. The negative control group or the solvent control (if using a solvent other than saline) consists of at least one eye.

6.4 Treatment of Eyes and Observations

6.4.1 Dosing procedure

a. After the equilibration period, record a zero reference measurement for corneal thickness and corneal opacity to serve as a baseline (i.e., time = 0). The fluorescein retention score determined at dissection is used as the baseline measurement.

b. Immediately following the zero reference measurement, apply the test substance to the eye (see Sections 6.4.1.1 and 6.4.1.2).

c. During the dosing procedure, remove the clamp holding the eye from the superfusion apparatus and place it on tissue paper with the cornea facing upwards.

d. Apply the test material for a total of 10 seconds and then rinse the eye with 20 mL isotonic saline at room temperature.

e. After the rinse step, return the eye to the superfusion apparatus.

Liquid test substances

Apply a liquid test substance at 0.03 mL with a micropipettor such that the entire surface of the cornea is covered with the test substance.

Solid test materials
If necessary, grind solid test substances into a fine powder with a mortar and pestle, or comparable grinding tools. Apply 0.03 g of a solid test substance evenly over the entire surface of the cornea.

6.4.2 Endpoint observations

a. Examine the control and test eyes at 30, 75, 120, 180, and 240 minutes (± 5 minutes) after treatment using the criteria and scoring system as indicated in Section 6.4.2.1.

b. Corneal opacity, corneal thickness, and any morphological effects should be evaluated at each time point, while fluorescein retention is determined only at the 30-minute time point.

c. After the final (240 minutes) examination, immerse all eyes in 4% neutral buffered formaldehyde for preservation for possible histopathological examination (if necessary).

d. To maximize the likelihood of obtaining reproducible results, reference photographs for all subjective endpoints (i.e., corneal opacity, fluorescein retention, morphological effects, histopathology) should be readily available.

Criteria and scoring system
The following criteria and scoring system are applied for the assessment of possible effects:

- Corneal swelling is expressed as a percentage and is calculated according to the following formula:

$$\left(\frac{\textit{corneal thickness at time } t \;-\; \textit{corneal thickness at time} = 0}{\textit{corneal thickness at time} = 0} \right) \times 100$$

The mean percentage of swelling for all test eyes is calculated for all observation time points. Based on the highest mean score for corneal swelling, as observed at any time point, an overall category score is then given for each test substance.

- Corneal opacity is calculated by using the area of the cornea that is most densely opacified for scoring.

Score	*Observation*
0 =	No opacity
0.5 =	Very faint opacity
1 =	Scattered or diffuse areas; details of the iris are clearly visible
2 =	Easily discernible translucent area; details of the iris are slightly obscured
3 =	Severe corneal opacity; no specific details of the iris are visible; size of the pupil is barely discernible
4 =	Complete corneal opacity; iris invisible

The mean corneal opacity value for all test eyes is calculated for all observation time points.

- Fluorescein retention
  The mean fluorescein retention value for all test eyes is calculated for the 30-minute observation time point only. When test substances have adhered to the cornea, fluorescein retention can be determined whenever the test substance has sufficiently loosened. The following scale is used for scoring:

Score	*Observation*
0 =	No fluorescein retention
0.5 =	Very minor single cell staining
1 =	Single cell staining scattered throughout the treated area of the cornea
2 =	Focal or confluent dense single cell staining
3 =	Confluent large areas of the cornea retaining fluorescein

- Morphological effects include "pitting" of corneal epithelial cells, "loosening" of epithelium, "roughening" of the corneal surface and "sticking" of the test substance to the cornea. These findings can vary in severity and may occur simultaneously. The classification of these findings is subjective according to the interpretation of the investigator. On the basis of severity of the observed findings, these effects are divided into four categories: 1 = none; 2 = slight; 3 = moderate; 4 = severe.
- A histopathological evaluation of the corneal tissue should be included when the standard ICE endpoints (i.e., corneal opacity, swelling, and fluorescein retention) produce borderline results. A standardized scoring scheme using the formal language of pathology to describe any effects should be included.

7.0 Evaluation of Test Results

Results from the three test method endpoints, corneal opacity, corneal swelling, and fluorescein retention should be evaluated separately (as in Section 9.0), and also combined to generate an Irritancy Classification for a test material (as in Section 10.0).

8.0 Criteria for an Acceptable Test

A test is considered acceptable if the negative and positive controls give an Irritancy Classification that falls within nonirritating and severely irritating, respectively

9.0 Data Interpretation

Interpretation of corneal thickness, corneal opacity, and fluorescein retention using four irritancy categories is done according to the following scales:

9.1 Corneal Thickness

Mean Corneal Swelling (%)	Category
0 to 5	I
> 5 to 12	II
> 12 to 18 (>75 minutes after treatment)	II
> 12 to 18 (≤75 minutes after treatment)	III
> 18 to 26	III
> 26 to 32 (>75 minutes after treatment)	III
> 26 to 32 (≤75 minutes after treatment)	IV
> 32	IV

9.2 Corneal Opacity

Mean Maximum Opacity Score	Category
0.0–0.5	I
0.6–1.5	II
1.6–2.5	III
2.6–4.0	IV

9.3 Fluorescein Retention

Mean Fluorescein Retention Score at 30 minutes post-treatment	Category
0.0–0.5	I
0.6–1.5	II
1.6–2.5	III
2.6–3.0	IV

10.0 Assessment of the Eye Irritancy

The irritancy classification for a test substance is assessed by reading the irritancy classification that corresponds to the combination of categories obtained for corneal swelling, corneal opacity, and fluorescein retention, as presented in the scheme below.

Classification	Combinations of the 3 Endpoints
Severely Irritating	3 x IV
	2 x IV, 1 x III
	2 x IV, I x II*
	2 x IV, I x I*
	Corneal opacity ≥ 3 at 30 min (in at least 2 eyes)
	Corneal opacity = 4 at any time point (in at least 2 eyes)
	Severe loosening of the epithelium (in at least 1 eye)

* Combinations less likely to occur.

11.0 Study Report

The test report should include the following information, if relevant to the conduct of the study:

Test and Control Substances

- Chemical name(s) such as the structural name used by the Chemical Abstracts Service (CAS), followed by other names, if known;
- The CAS Registry Number (RN), if known;
- Purity and composition of the substance or preparation (in percentage[s] by weight), to the extent this information is available;

- Physicochemical properties such as physical state, volatility, pH, stability, chemical class, water solubility relevant to the conduct of the study;
- Treatment of the test/control substances prior to testing, if applicable (e.g., warming, grinding);
- Stability, if known.

Information Concerning the Sponsor and the Test Facility

- Name and address of the sponsor, test facility, and study director;
- Identification of the source of the eyes (i.e., the facility from which they were collected);
- Storage and transport conditions of eyes (e.g., date and time of eye collection, time interval prior to initiating testing);
- If available, specific characteristics of the animals from which the eyes were collected (e.g., age, sex, strain, weight of the donor animal).

Justification of the Test Method and Protocol Used

Test Method Integrity

- The procedure used to ensure the integrity (i.e., accuracy and reliability) of the test method over time (e.g., periodic testing of proficiency substances, use of historical negative and positive control data).

Criteria for an Acceptable Test

- If applicable, acceptable concurrent benchmark control ranges based on historical data.

Test Conditions

- Description of test system used:
- Slit-lamp microscope used (e.g., model);
- Instrument settings for the slit-lamp microscope used:
- Information for the chicken eyes used, including statements regarding their quality;
- Details of test procedure used;
- Test concentration(s) used;
- Description of any modifications of the test procedure;
- Reference to historical data of the model (e.g., negative and positive controls, proficiency substances, benchmark substances);
- Description of evaluation criteria used.

Results

- Description of other effects observed;
- If appropriate, photograph of the eye.

Discussion of the Results

Conclusion

A Quality Assurance Statement for Good Laboratory Practice (GLP)-Compliant Studies

- This statement indicates all inspections made during the study, and the dates any results were reported to the study director. This statement also serves to confirm that the final report reflects the raw data.

If GLP-compliant studies are performed, then additional reporting requirements provided in the relevant guidelines (e.g., OECD 1998; EPA 2003b, 2003c; FDA 2003) should be followed.

Appendix B5

ICCVAM-Recommended Protocol for Future Studies Using the Isolated Rabbit Eye (IRE) Test Method

ICCVAM recommends this IRE test method protocol for nonregulatory, validation, or optimization studies to facilitate collection of consistent data and expand the available database. Exceptions and/or changes to the test method protocol should be accompanied by a scientific rationale.

This page intentionally left blank

PREFACE

The information included in this protocol was derived from protocols used at Unilever Safety and Environmental Assurance Centre, Colworth, United Kingdom (Jones P, personal communication) and at SafePharm Laboratories, Derby, United Kingdom (Whittingham A, personal communication) and from evaluation of IRE protocols reported in the literature (Burton et al. 1981; Price and Andrews 1985; Whittle et al. 1992; INVITTOX 1994; Balls et al. 1995; Chamberlain et al. 1997; Cooper et al. 2001; Jones et al. 2001; Guerriero et al. 2004). Future studies using the IRE test method could include further characterization of the usefulness or limitations of the IRE in a weight-of-evidence approach for regulatory decision-making. Users should be aware that the proposed test method protocol could be revised based on any additional optimization and/or validation studies that are conducted in the future. ICCVAM recommends that test method users consult the NICEATM-ICCVAM website (http://iccvam.niehs.nih.gov/) to ensure use of the most current test method protocol.

1.0 Purpose and Applicability

The purpose of the protocol is to provide details of the essential procedures required to (1) insure induction of corneal irritancy in the enucleated eye of the rabbit by a potentially irritating test substance, (2) evaluate the degree of irritancy, and (3) enable assignment of an appropriate regulatory classification on the potential ocular irritancy of a test substance. Toxic effects in the isolated rabbit eye are measured by (1) subjective assessment of changes in corneal opacity, (2) uptake of fluorescein dye within the cornea (permeability), (3) increased corneal thickness (swelling), and (4) corneal epithelial changes (pitting, sloughing, mottling, etc.) evaluated macroscopically or by slit-lamp. The opacity, swelling, and permeability assessments following exposure to a test substance are assessed individually and are used to determine if the test substance has the potential to induce ocular corrosion or severe irritation.

The focus of this protocol is on the use of the IRE test method for the detection of ocular corrosives and severe irritants, as defined by the U.S. Environmental Protection Agency (EPA 2003a), European Union (EU 2001), and United Nations Globally Harmonized System (GHS) of Classification and Labelling of Chemicals (UN 2007). However, the IRE test method is not currently considered to be adequately validated for classification of ocular irritancy as defined by EPA (2003a), EU (2001), and GHS (UN 2007).

ICCVAM recommends this IRE test method protocol for nonregulatory, validation, or optimization studies to facilitate collection of consistent data and expand the available database. Exceptions and/or changes to the test method protocol should be accompanied by a scientific rationale.

2.0 Safety and Operating Precautions

All procedures with rabbit eyes should follow the institution's applicable regulations and procedures for handling of human or animal substances, which include, but are not limited to, tissues and tissue fluids. Universal laboratory precautions are recommended, including the use of laboratory coats, eye protection, and gloves. If available, additional precautions required for specific study substances should be identified in the Material Safety Data Sheet for that substance.

3.0 Material, Equipment, and Supplies

3.1 Source of Rabbit Eyes

Rabbits should not be bred and sacrificed specifically for use in the IRE test method. Eyes should be obtained from healthy New Zealand White rabbits of either sex weighing 2.5-4.0 kg. To reduce

animal usage, rabbits may be obtained from intra- or extramural laboratories where rabbits may have been used for other purposes (e.g., isolated organ bath, controls) that would not affect ocular tissue, or from a local abattoir where rabbits are typically sacrificed as a food source. Isolated rabbit eyes of exceptional quality without corneal surface defects may be purchased and shipped overnight from a reputable source such as Pel-Freeze Biologicals (Edelhauser H, personal communication). For rapid transfers from laboratory to laboratory within close proximity to each other (1 hour or less), the eyes may be wetted with isotonic saline, or an appropriate buffer (e.g., HBSS without phenol red), secured in position in a hydrated container at room temperature and sealed for shipment. For longer shipments (up to 4 hours), storage at 4°–8°C is recommended. For overnight shipment, storage at 4°–8°C in isotonic saline, or an appropriate buffer (e.g., HBSS without phenol red) with optional antibiotics and an antimycotic is recommended (Vafeas et al. 1998; Chandrasekher et al. 2002).

3.2 Equipment and Supplies

- Chamber, superfusion, Perspex® or similar inert material, water-jacketed temperature-controlled at 32 ± 1.5°C (Burton et al. 1981)
- Drip tubes made from stainless steel tubing (for saline rinsing of cornea)
- Forceps, tissue
- Holders, eye, Perspex or stainless steel with moveable upper jaw
- Magnifying glass
- Plastic tubing, medical or food-grade to supply lines for saline drip tubes
- Pump, peristaltic, 0.1-0.4 mL/minute flow rate adjusted to pump saline in flask in water bath through the saline drip tube
- Pump, peristaltic, approximately 4 L/minute flow rate to pump water through superfusion apparatus and maintain temperature control
- Scissors, fine surgical
- Scissors, surgical enucleation
- Slit-lamp biomicroscope or equivalent
- Optical or ultrasonic pachymeter to quantitatively measure corneal thickness. The optical pachymeter is used in conjunction with the slit-lamp whereas the ultrasonic pachymeter is a stand-alone device.
- Syringe, plastic, 20 ml for eye wash
- Syringe for sodium pentobarbitone administration
- Thermistor (e.g., YSI thermistor, Yellow Spring Co., Inc, OH, USA) to check saline drip temperature
- Tubing, food or medical grade for pumping saline and for connecting to water supply in circulator, sizes may vary with hose fittings
- Water bath, recirculating (capable of maintaining a temperature of 32 ± 1.5°C)
- Weigh Boat, plastic disposable, or a 1 mL disposable plastic syringe with the narrow tip removed

3.3 Solutions

Solutions may be obtained ready prepared from a commercial supplier. Follow the manufacturer's recommendations with regard to storage temperature and shelf life of stock solutions. If necessary, prepare assay solutions volumetrically and store at room temperature unless otherwise noted. Buffers or solutions containing glucose or temperature-sensitive components should be stored at 4°–8°C and equilibrated to room temperature just before use.

- Buffers, physiological salt solution (Hank's, Krebs, etc.)
- Fluorescein, sodium BP (1%–2%), prepared fresh on the day of the experiment

- Physiological (isotonic) saline (0.9%)
- Sodium pentobarbitone
- Sterile deionized/distilled water

4.0 Test Substance Preparation

4.1 Liquid Test Substances

Apply liquid test substances undiluted, although liquid test substances may be diluted if deemed necessary (e.g., as part of the study design). Isotonic saline or standard buffered physiological salt solutions (e.g., Hank's, Krebs, etc.) are the recommended solvents. The appropriateness of solvents other than isotonic saline or standard buffered physiological salt solutions must be demonstrated.

4.2 Solid, Particulate or Granular Test Substances

Grind solid, particulate or granular test substances as fine as possible in a mortar and pestle. The material may be sprinkled on the cornea using a weigh boat or gently compacted in a syringe with the narrow tip removed and then applied. The substance may need to be prewetted and the pH measured (Guest R, personal communication).[2]

5.0 Controls

5.1 Negative Control

A negative control (e.g., distilled water, isotonic saline, other assay medium) is included in each experiment in order to detect non-specific changes in the test system, as well as to provide a baseline for the assay endpoints, and ensure that the assay conditions do not inappropriately result in an irritant response.

5.2 Solvent/Vehicle Controls

Solvent/vehicle controls are recommended when solvents/vehicles other than deionized/distilled water, saline, or other assay medium are used to dissolve test substances, in order to demonstrate that the solvent/vehicle is not interfering with the test system.

5.3 Positive Controls

A known ocular irritant is included in each experiment to verify that an appropriate response is induced. If the IRE assay is being used only to identify corrosive or severe irritants, then the positive control should be a reference substance that induces a severe response *in vivo* as well as in the IRE. However, to ensure that variability in the positive control response across time can be assessed, the magnitude of the severe response should not be excessive. The selection of positive control test substances should be based on the availability of high quality *in vivo* data. For test substances being tested in liquid or solid form, a corresponding liquid or solid positive control should be included in the test.

5.4 Benchmark Controls

Benchmark controls may be useful to demonstrate that the test method is functioning properly for detecting the ocular irritancy potential of substances of a specific chemical class or a specific range of

[2] Since the isolated eye has less moisture content than the eye *in situ* and compounds that dissociate or hydrolyze could produce false negatives due to reduced dissociation or hydrolysis in the isolated eye.

responses, or for evaluating the relative irritancy potential of an ocular irritant. Appropriate benchmark controls should be chosen based on high quality *in vivo* test results and have the following properties:

- A consistent and reliable source(s)
- Structural and functional similarity to the class of substance being tested
- Known physical/chemical characteristics
- Supporting data on known effects in the *in vivo* rabbit eye test
- Known potency in the range of the desired response

6.0 Experimental Design

6.1 Treatment Groups

Use at least three eyes for each test substance and three eyes for each of the controls in the study. The controls must be tested concurrently with the test substance.

6.2 Eye Selection and Preparation

a. For each assay, use a number of animals adequate to provide at least three eyes for each test substance and three eyes for each of the various controls considering rejection levels of suitable eyes to be as high as 25% in some cases. All isolated eyes should be randomly distributed within experimental groups, particularly when both eyes from the same rabbit are used.

b. Examine the rabbit corneas *in vivo* macroscopically and microscopically and, if the eyes are accepted to be free of imperfections, measure the initial corneal thickness (Reading T-2; *in vivo* reading, if possible). In some cases, rabbits may be euthanized commercially and this *in vivo* reading may not be possible. In those cases, a pre-equilibration reading (T-1) is sufficient (**Section 6.3**).

c. Euthanize the rabbits humanely by injection of a lethal dose of sodium pentobarbitone into the marginal ear vein. Follow the institution's applicable regulations and procedures regarding euthanasia. A typical lethal dose for rabbits is 200 mg/kg, administered intravenously. Remove each eye by dissection of the conjunctiva and the optic nerve (leave approximately a 5–10 mm section of the nerve to prevent loss of intraocular pressure) after deflection of the nictitating membrane.

d. Rinse the orbit occasionally with saline during the dissection to prevent drying and afterwards to remove any adherent tissue.

e. Ship eyes obtained from external sources in saline or an appropriate buffer (e.g., HBSS without phenol red) at an appropriate temperature (4 -8°C for shipment over periods greater than 1 hour or 25 ± 5°C for shipment over a period of 1 hour or less) in a humidified, sealed container to prevent drying of the corneas. For longer shipments periods (e.g., overnight), antibiotics with an antimycotic may be needed (Vafeas et al. 1998; Chandrasekher et al. 2002).

f. The method of euthanasia and any prior pharmacological or physiological treatment of the animals for eyes shipped from external sources are noted and the eyes are inspected microscopically and macroscopically for imperfections.

g. If there is any doubt that the cornea is free of imperfections, apply a 1%–2% solution of sodium fluorescein BP followed immediately by a gentle, but thorough rinse with

physiological saline (a time insufficient for actual penetration of fluorescein) to identify corneal imperfections.

h. Once they have been inspected and are deemed to be free of corneal defects, the eyes are clamped into the holders (one eye per holder) with the cornea in a vertical position, without altering the *in vivo* orientation of the eyeball, and placed in the maintenance chamber (see **Figure 6-1** and **Figure 6-2**).

i. The eyes are equilibrated for 30 to 45 minutes at 32 ± 1.5°C.

Figure 6-1 Isolated Rabbit Eye Equilibration Apparatus

Photo provided courtesy of R. Guest

Figure 6-2 Isolated Rabbit Eye Holder

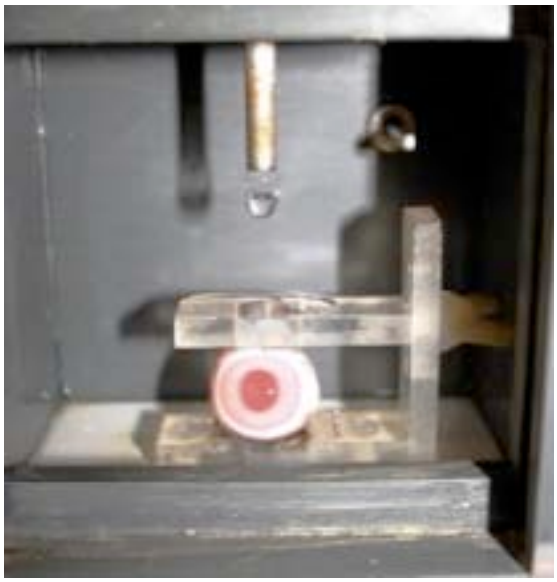

Photo provided courtesy of R. Guest

6.3 Pretreatment Measurements

a. Measure the corneal thickness (Reading T-1) before equilibration. Any eyes in which corneal swelling has exceeded 7% relative to *in vivo* values are discarded and replaced (Reading T-2; **Section 6.2**).

b. The corneal thickness is measured again after equilibration and just prior to application of the test substance. This will become Reading T0 (**Section 6.3**). If a significant amount of time (3 ± 1 hours) has elapsed between post-equilibration and application, any eyes that have swelling >7% relative to the post-equilibration value (T0) should be replaced. If an ultrasonic pachymeter is used which requires direct contact with the cornea, an initial measurement and a post-equilibration reading may be necessary to minimize the possibility of damage to the cornea (Guest R, personal communication).

6.4 Application of Test Substances

a. Remove the holder from the cell where the eye is held in a vertical position, then reposition the eye with the cornea in the horizontal plane (i.e., facing upward) and apply the test substance (premoistened, if necessary) directly on the corneal surface immediately.

b. For liquid substances, apply 0.1 mL of undiluted test substance using a syringe over as much of the entire corneal surface as possible.

c. For solid substances, sprinkle a volume of 0.1 mL (not exceeding 100 mg) of neat test substance pulverized to a fine powder or dust over the entire cornea using a plastic weigh boat or other means of delivery (e.g., from a 1 mL disposable syringe with the tip removed). Record the mean weight of material that is applied to each eye.

d. Adjust the concentration, volume or weight if necessary for compounds with known physical characteristics that may interfere with the test (e.g., viscous substances or solids that irreversibly adhere to the cornea and cannot be washed off).

e. Apply 0.1 mL of physiological saline (prewarmed to 32°C) to the control eye.

f. For liquid positive control substances, apply 0.1 mL using a syringe over as much of the entire corneal surface as possible.

g. For solid positive control substances, sprinkle 0.1 g pulverized to a fine powder or dust over the entire cornea using a plastic weigh boat or other means of delivery.

h. Allow the test substance, the positive control, and the negative control to remain in contact with the cornea for 10 ± 2 seconds.

i. Rinse each eye with 20 ml of physiological saline (prewarmed to 32°C) using a syringe and place the eye holder back in the cell of the maintenance chamber.

j. Return the saline drip tube to its original position to bathe the cornea between measurement periods.

k. Repeat these procedures for subsequent treated and control eyes.

6.5 Endpoint Observations

6.5.1 Corneal opacity and area

a. With the aid of the light source from the slit-lamp (diffuse illumination), examine each eye macroscopically at each time point (0.5, 1, 2, 3, 4 hours), assess the extent of corneal injury, noting signs of sloughing, mottling, pitting or other signs of epithelial damage. Identify focal areas for slit-lamp evaluation.

b. Examine each eye microscopically at each time point (0.5, 1, 2, 3 and 4 hours) using a slit-lamp set with a narrow slit width and score corneal opacity and area involvement according to the scoring system found in **Table 6-1**.

6.5.2 Corneal swelling

a. Measure corneal thickness using the depth measuring attachment or ultrasonic pachymeter before treatment (as described previously) and at each time point post-treatment.

b. Calculate corneal swelling based on the percent change in corneal thickness over time according to the following formula:
[(Corneal Thickness at Time T/Corneal Thickness at Time T0)-1] x 100%

6.5.3 Corneal epithelial observations

a. Examine the cornea macroscopically or by slit-lamp microscopically at each time point for sloughing, mottling, pitting or other signs of epithelial damage.

b. To maximize the likelihood of obtaining reproducible results, reference photographs for all subjective endpoints (i.e., corneal opacity, fluorescein retention, morphological effects, histopathology) should be readily available.

Table 6-1 Evaluation of Corneal Irritation[1]

Description	
Cornea	**Individual Score**
Normal cornea. Appears with the slit-lamp adjusted to a narrow slit image as having a bright gray line on the epithelial surface and a bright gray line on the endothelial surface with a marble-like gray appearance of the stroma.	0
Some loss of transparency. Only the anterior half of the stroma is involved as observed with an optical section of the slit-lamp. The underlying structures are clearly visible with diffuse illumination, although some cloudiness can be readily apparent with diffuse illumination.	1
Moderate loss of transparency. In addition to involving the anterior stroma, the cloudiness extends all the way to the endothelium. The stroma has lost its marble-like appearance and is homogenously white. With diffuse illumination, underlying structures are clearly visible.	2
Involvement of the entire thickness of the stroma with endothelium intact. With optical section, the endothelial surface is still visible. However, with diffuse illumination the underlying structures are just barely visible (to the extent that the observer is still able to grade flare and iritis, observe for pupillary response, and note lenticular changes).	3
Involvement of the entire thickness of the stroma with endothelium damaged. With the optical section, cannot clearly visualize the endothelium. With diffuse illumination, the underlying structures cannot be seen. Cloudiness removes the capability for judging and grading flare, iritis, lenticular changes, and pupillary response.	4
Corneal area	**Individual Score**
Normal cornea with no area of cloudiness	0
1% to 25% area of stromal cloudiness	1
26% to 50% area of stromal cloudiness	2
51% to 75% area of stromal cloudiness	3
76% to 100% area of stromal cloudiness	4
Overall Corneal Opacity/Area	**Product Score**
Corneal Opacity x Area[2]	Maximum of 16

[1] From: Hackett and McDonald (1991).

[2] The overall corneal opacity score is the product of the corneal opacity score and the corneal area score. The product of individual scores of 1 and 4 (Product Score of 4) or 2 and 2 (Product Score of 4), for example, would each qualify for a severe irritant rating based on the overall corneal opacity/area score.

c. Additional endpoints such as histopathology to look at each of the various corneal tissue layers (i.e., epithelium, Bowman's layer, stroma, Descemet's layer, and endothelium) or confocal microscopy with live/dead cell staining may be used to corroborate or to re-evaluate the actual depth of injury, particularly where equivocal results may have been obtained by use of existing endpoints or where the irritancy of a substance falls into the interface between a severe and nonsevere irritant. A standardized scoring scheme using the formal language of pathology to describe any effects should be included.

6.5.4 Fluorescein penetration

- At the end of the 4-hour testing period or earlier score each cornea for fluorescein penetration using a 10 ± 2.0 seconds application followed by a thorough rinse with physiological saline or negative control buffer (**Table 6-2**).

Table 6-2 Fluorescein Penetration Scoring System[1]

Description	**Individual Scores (Area/Intensity)**
Negligible — No staining.	0
Slight staining confined to small focal area. Some loss of detail in underlying structures with diffuse illumination.	1
Moderate staining confined to a small focal area. Some loss of detail in underlying structures on diffuse illumination.	2
Marked staining involving a larger portion of the cornea. Underlying structures are barely visible but not completely obliterated with diffuse illumination.	3
Extreme staining with no visibility of underlying structures.	4
Fluorescein Penetration	**Product Score**
Fluorescein Area x Intensity	**Maximum of 16**

[1] From: Hackett and McDonald (1991).

7.0 Evaluation of Test Results

Using the scores obtained from the endpoints evaluated (as described above), determine if the test substance meets the criteria for a corrosive or severe ocular irritant using the decision criteria provided in **Table 8-1**.

8.0 Criteria for an Acceptable Test

- If, in the course of evaluation of three eyes, there is significant disagreement in the results between eyes, repeat the experiment and calculate the mean for all six determinations to assess overall damage.
- Changes in control eyes greater than 7% during the 4-hour observation period warrant rejection of the experiment.
- A test is considered acceptable if the negative control produces either no effect or only slight or marginal effects on the various parameters and the positive control produces a severe irritant effect as defined in **Table 8-1**.

Table 8-1 Decision Criteria for Determination of Severe Irritants: Overall Scoring System for Corneal Damage and Irritation[1]

Ocular Parameter	Cut-off Value to Detect Severe Eye Irritants
Maximum Corneal Opacity[2] Cloudiness x Area	Greater than or equal to a score of 3
Maximum Fluorescein Uptake[3] Intensity x Area	Greater than or equal to a score of 4
Mean Corneal Swelling[4] 0.5 hours 1 hour 2 hours 3 hours 4 hours	Greater than or equal to 25%
Corneal Epithelial Observations[5]	Any pitting, mottling, or sloughing

[1] From: Guerriero et al., 2002

[2] Represents maximum score obtained in 3 eyes

[3] Represents maximum score obtained in 3 eyes

[4] Represents mean swelling calculated for 3 eyes

[5] Represents information obtained for any single animal

- Control charts should be used to monitor historical responses and calculate acceptable ranges for negative and positive controls, and benchmark controls when used, over time and across laboratories. These ranges should be updated frequently to adjust test acceptance criteria for individual control substances. An acceptable test would then have positive or benchmark controls that fell within these acceptable ranges.

9.0 Data Interpretation

Test substances meeting or exceeding the criteria for severe irritation defined in **Table 8-1** in an acceptable test (as defined in **Section 8.0**) are identified as severe irritants. Test substances not meeting these cut-off criteria in an acceptable test are identified as nonsevere irritants. Benchmark substances are recommended for comparing the responses of test substances of different product or chemical classes. It may be useful to carefully evaluate the pattern of responses in the four endpoints.

10.0 Study Report

The test report should include the following information, if relevant to the conduct of the study:

Test and Control Substances

- Chemical name(s) such as the structural name used by the Chemical Abstracts Service (CAS), followed by other names, if known
- The CAS Registry Number (RN), if known
- Purity and composition of the substance or preparation (in percentage(s) by weight)
- Physicochemical properties such as physical state, volatility, pH, stability, chemical class, water solubility relevant to the conduct of the study
- Treatment of the test/control substances prior to testing, if applicable (e.g., warming, grinding)
- Stability, if known

Information Concerning the Sponsor and the Test Facility

- Name and address of the sponsor
- Name and address of the facility
- Name and address of the Study Director

Justification of the Test Method and Protocol Used

Test Method Integrity

- The procedure used to ensure the integrity (i.e., accuracy and reliability) of the test method over time (e.g., periodic testing of proficiency substances, use of historical negative and positive control data)

Criteria for an Acceptable Test

- Acceptable concurrent negative control ranges based on historical data
- Acceptable concurrent positive control ranges based on historical data
- If applicable, acceptable concurrent benchmark control ranges based on historical data

Test Conditions

- Description of test system used
- Complete supporting information for the enucleated rabbit eyes used including statements regarding their quality
- Details of test procedure used
- Test concentration(s) used
- Description of any modifications of the test procedure
- Reference to historical data of the model (e.g., negative and positive controls, proficiency substances, benchmark substances)
- Description of evaluation criteria used

Results

- Tabulation of data from individual test samples (e.g., irritancy scores for the test substance and the various controls, including data from replicate repeat experiments as appropriate, and means and ± the standard deviation for each trial)

Description of Other Effects Observed

Discussion of the Results

Conclusion

A Quality Assurance Statement for Good Laboratory Practice (GLP)-Compliant Studies

- This statement indicates all inspections made during the study, and the dates any results were reported to the Study Director. This statement also serves to confirm that the final report reflects the raw data.

If GLP-compliant studies are performed, then additional reporting requirements provided in the relevant guidelines (e.g., OECD 1998; EPA 2003b, 2003c; FDA 2003) should be followed.

Preface

Accidental contact with hazardous chemicals frequently causes eye injury and visual impairment. United States and international regulatory agencies currently use the Draize rabbit eye test (Draize et al. 1944) to identify potential ocular hazards associated with chemicals. The U.S. Consumer Product Safety Commission (CPSC), U.S. Environmental Protection Agency (EPA), U.S. Food and Drug Administration, and U.S. Occupational Safety and Health Administration have testing requirements and guidelines for assessing the ocular irritation potential of substances such as pesticides, household products, pharmaceuticals, cosmetics, and agricultural and industrial chemicals.

Although ocular safety assessment has clearly helped to protect consumers and workers, concerns have been raised about the humane aspects of the Draize rabbit eye test. Regulatory authorities have adopted various modifications that reduce the number of animals used and the potential pain and distress associated with the procedure. Significant progress has been made during the last decade. Now tests require only one to three rabbits, compared to six rabbits per test in the original protocol. Provisions have been added that allow for animals with severe lesions or discomfort to be humanely euthanized.

The Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) previously evaluated the validation status of the bovine corneal opacity and permeability (BCOP), isolated chicken eye (ICE), isolated rabbit eye (IRE), and hen's egg test–chorioallantoic membrane (HET-CAM) test methods for the identification of ocular corrosives or severe (irreversible) ocular irritants. ICCVAM used the EPA (2003a), United Nations Globally Harmonized System of Classification and Labelling of Chemicals (GHS) (UN 2007), and European Union (EU 2001) regulatory hazard classification systems. In ICCVAM's assessment, the performance of the BCOP and ICE test methods substantiated their use in testing some substances for regulatory hazard classification. The IRE and HET-CAM test methods lacked sufficient performance and/or sufficient data to substantiate their use for regulatory hazard classification.

ICCVAM recommended that the BCOP and ICE test methods should be used in a tiered-testing strategy in which positive substances can be classified as ocular corrosives or severe irritants without animal testing. In accordance with the ICCVAM Authorization Act of 2000 (Public Law 106-545), these recommendations were made available to the public and provided to U.S. Federal agencies for consideration in the *ICCVAM Test Method Evaluation Report – In Vitro Ocular Toxicity Test Methods for Identifying Severe Irritants and Corrosives* (ICCVAM 2006b). The ICCVAM recommendations were accepted by U.S. Federal agencies, and *in vitro* test methods may now be used instead of the Draize rabbit eye test for certain regulatory testing purposes.

ICCVAM is now reviewing the validation status of these *in vitro* test methods for identification of nonsevere ocular irritants (that is, those that induce reversible ocular damage [EPA Category II, III; EU Category R36, GHS Category 2A, 2B]) and substances not classified as irritants (GHS NC or Not Labeled, EPA Category IV, FHSA Not Labeled, or EU Not Labeled) according to the GHS (UN 2007), EPA (EPA 2003a), FHSA (FHSA 2005), and EU (EU 2001) classification systems. The Federal Hazardous Substances Act (FHSA) classification system (FHSA 2005) as defined in the "Test for Eye Irritants" (i.e., "Irritant" or Not Labeled [as an irritant]) and published in 16 CFR 1500.42 (CPSC 2003) is also provided in the current background review documents. The FHSA classification system was not used in the previous analyses of test methods used for the identification of severe ocular irritants or corrosives because the FHSA classification is limited to irritants and is not intended to identify corrosive substances or to differentiate between severe and nonsevere irritants.

Accordingly, the National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) and the ICCVAM Ocular Toxicity Working Group (OTWG) prepared draft background review documents that summarize the current validation status of each test method based on published studies and other data and information submitted in response to a

June 7, 2007, *Federal Register* request (72 FR 31582, available at http://iccvam.niehs.nih.gov/SuppDocs/FedDocs/FR/FR_E7_10966.pdf). The background review documents form the basis for draft ICCVAM test method recommendations, which are provided in separate documents. Liaisons from the European Centre for the Validation of Alternative Methods and the Japanese Center for the Validation of Alternative Methods will provide input and contribute to the OTWG throughout the evaluation process.

An international independent scientific peer review panel (Panel) met in public session on May 19–21, 2009, to develop conclusions and recommendations on the *in vitro* BCOP, ICE, IRE, and HET-CAM test methods. The Panel included expert scientists nominated by the European Centre for the Validation of Alternative Methods and the Japanese Center for the Validation of Alternative Methods. We anticipate that these organizations can use the subsequent independent Panel report to deliberate and develop their own test method recommendations (ICCVAM Peer Review Panel Report [ICCVAM 2009] available to the public for comment on July 12, 2009). The Panel considered these background review documents and evaluated the extent to which the available information supports the draft ICCVAM test method recommendations.

ICCVAM provided the Scientific Advisory Committee on Alternative Toxicological Methods (SACATM) with the draft BRD and draft Test Method Evaluation Report, the Panel's report, and all public comments. SACATM discussed these at their June 25-26, 2009, meeting, where public stakeholders were given another opportunity to comment. After SACATM's meeting, ICCVAM considered the SACATM comments, the Panel report, and all public comments before finalizing the background review document and test method recommendations. These recommendations will be forwarded to Federal agencies for their consideration and acceptance decisions where appropriate.

We gratefully acknowledge the organizations and scientists who provided data and information for this document. We also acknowledge the efforts of those individuals who helped prepare this background review document, including the following staff from the NICEATM support contractor, Integrated Laboratory Systems, Inc.: David Allen, Jon Hamm, Nelson Johnson, Brett Jones, Elizabeth Lipscomb, Linda Litchfield, Steven Morefield, Gregory Moyer, Catherine Sprankle, and Jim Truax. We also thank the members of the ICCVAM Ocular Toxicity Working Group, chaired by Karen Hamernik, Ph.D. (U.S. EPA) and Jill Merrill, Ph.D. (U.S. Food and Drug Administration), and ICCVAM representatives who reviewed and commented on draft versions. We also thank Valerie Zuang, Ph.D., and Hajime Kojima, Ph.D., liaisons to the Ocular Toxicity Working Group from the European Centre for the Validation of Alternative Methods and the Japanese Center for the Validation of Alternative Methods, respectively, for their participation.

Executive Summary

In October 2003, the U.S. Environmental Protection Agency (EPA) submitted to the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) a nomination requesting the evaluation of several activities related to reducing, refining, and replacing the use of rabbits in the current *in vivo* Draize rabbit eye test (69 FR 13859 [March 24, 2004]). In response to this nomination, ICCVAM evaluated the validation status of the bovine corneal opacity and permeability (BCOP), hen's egg test–chorioallantoic membrane (HET-CAM), isolated chicken eye (ICE), and isolated rabbit eye (IRE) test methods. To evaluate how well these test methods identify ocular corrosives and severe irritants, ICCVAM used the EPA (2003a), European Union (EU 2001), and United Nations Globally Harmonized System of Classification and Labelling of Chemicals (GHS) (UN 2007) classification systems.

ICCVAM considered the performance of two of these *in vitro* test methods, the BCOP and the ICE, to be sufficient to support their use in testing certain types of substances for regulatory hazard classification. The IRE and HET-CAM test methods lacked sufficient performance and/or sufficient data to support their use for regulatory hazard classification. ICCVAM recommended that the BCOP and ICE test methods should be used in a tiered-testing strategy that would classify positive substances as ocular corrosives or severe irritants without animal testing. These recommendations were accepted by U.S. Federal agencies, and, as a result, *in vitro* test methods may now be used instead of conventional tests for certain regulatory testing purposes.

ICCVAM is now reviewing the validation status of these *in vitro* test methods to identify nonsevere ocular irritants (those that cause reversible ocular damage [EPA Category II and III; EU R36; GHS Category 2A and 2B]) and substances not classified as irritants (EPA Category IV; EU Not Labeled; GHS Not Classified) according to the EPA (2003a), EU (2001), and GHS (UN 2007) classification systems. The U.S. Federal Hazardous Substances Act (FHSA) classification system, which is based on the testing guidelines and associated criteria included in 16 CFR 1500.42 (CPSC 2003), is also included in these evaluations. The FHSA classification system was not used in the original analyses (ability of the test methods to identify ocular corrosives and severe irritants) because the FHSA ocular hazard category that is assigned based on results from the Draize rabbit eye test (Draize et al. 1944) does not distinguish between ocular corrosives and severe irritants and less severe irritants. For this reason, an evaluation to identify ocular corrosives and severe irritants using the FHSA classification system was not possible.

- Because the FHSA classification system (2005) is based on a sequential testing strategy that uses up to 18 animals, only a small percentage of the substances in the BCOP database would be classifiable if the FHSA criteria were strictly applied. To maximize the number of substances included in these analyses, "proportionality" criteria were applied for the purpose of assigning an FHSA classification to test results that would require additional testing according to the FHSA sequential testing strategy. These "proportionality" criteria (FHSA-20% and FHSA-67%) are as follows:
- FHSA-20% is based on the proportion of positive animals needed to identify a substance as an irritant using the FHSA sequential testing strategy, where 20% of the animals must demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled if ≤1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there were ≥1 positive animal in a 3- to 5-animal test or ≥2 positive animals in a 6-animal test.
- FHSA-67% is based on the proportion of positive animals needed to identify a substance as an irritant using the "first test" of the FHSA sequential testing strategy, where 67% of the animals must demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled as an irritant if ≤1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there

were ≥2/3, 3/4, 4/5, or 4/6 positive animals. If 1/3, 1/4, 2/4, 1/5, 2/5, 3/5, 2/6, or 3/6 animals were positive, further testing would be required.

Together, the National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) and the ICCVAM Ocular Toxicity Working Group prepared draft background review documents (BRDs) that summarize the available data and information regarding the validity (usefulness and limitations) of each test method. This BRD summarizes all available information for the BCOP test method and its current validation status, including what is known about its reliability and accuracy, and the scope of the substances tested. Original data for the BCOP test method will be maintained for future use so that these performance statistics may be updated as additional information becomes available.

BCOP Test Method Protocol

The BCOP test method is an *in vitro* eye irritation test method that uses isolated bovine eyes that are byproducts from processing plants. Changes in corneal opacity and permeability are assessed as a measure of test substance damage. To determine opacity, the amount of light transmitted through the cornea is measured with an opacitometer. To determine permeability, the amount of sodium fluorescein dye that passes through all corneal cell layers is measured with a visible light spectrophotometer. Both permeability and opacity are used to calculate an *in vitro* irritancy score (IVIS) that is used to assign an *in vitro* irritancy classification, which predicts the potential of a test substance to cause *in vivo* ocular irritation.

Validation Database

An online literature search was conducted to support the initial evaluation of the validation status of the BCOP test method. The search identified four publications containing BCOP test method results. However, none of these publications included raw data or referenced *in vivo* data. Some of these publications also included data from earlier studies that were already in the validation database. ICCVAM received the BCOP test results for 66 antimicrobial cleaning products (AMCPs) in a submission that describes a non-animal approach for evaluating eye irritation potential and labeling requirements for AMCPs. The previous validation database for the BCOP test method (ICCVAM 2006a) was updated to include these results.

The updated BCOP validation database contains a total of 211 substances, including 135 commercial products or formulations. The most commonly tested chemical classes are alcohols, carboxylic acids, esters, formulations, heterocyclic compounds, hydrocarbons, ketones, and onium compounds. The formulations tested include hair shampoos, personal care cleansers, detergents, bleaches, insect repellents, petroleum products, and fabric softeners. The most commonly tested product classes are chemical/synthetic intermediates, cleaners, drugs/pharmaceuticals/therapeutic agents, petroleum products, solvents, shampoos, and surfactants.

In order to calculate the appropriate EPA (2003a), EU (2001), FHSA (2005), and GHS (UN 2007) ocular irritancy hazard classifications, detailed *in vivo* data consisting of cornea, iris, and conjunctiva scores for each animal at 24, 48, and 72 hours following test substance administration and/or assessment of the presence or absence of lesions at 7, 14, and 21 days are needed. Some of the test substances had only limited *in vivo* data and could not be used to evaluate test method accuracy and reliability. To maximize the number of substances included in the FHSA analyses, "proportionality" criteria (FHSA-20% and FHSA-67%), as outlined above, were applied for the purpose of assigning a FHSA classification to test results that would require additional testing according to the FHSA sequential testing strategy.

BCOP Test Method Accuracy

Identification of All Ocular Hazard Categories

ICCVAM evaluated how well the BCOP test method identified all categories of ocular irritation potential as defined by the EPA (2003a), GHS (UN 2007), and EU (2001) classification systems. Because the FHSA classification system does not distinguish between ocular corrosives and severe irritants and less severe irritants, an evaluation for all ocular hazard categories using the FHSA classification system was not possible.

As shown in **Table 1**, overall correct classifications ranged from 49% (91/187) to 55% (102/187) when using the entire database, depending on the hazard classification system used. Using different decision criteria to identify ocular corrosive/severe irritants (IVIS ≥ 75), based on the AMCP BRD (2008), instead of IVIS ≥ 55.1 as outlined in the ICCVAM BCOP BRD (2006a), does not improve test method performance.

Distinguishing Substances Not Labeled as Irritants from All Other Hazard Categories

ICCVAM also evaluated how well the BCOP test method distinguished substances not labeled as irritants (EPA Category IV, GHS Not Classified, EU Not Labeled, FHSA Not Labeled) from all other ocular hazard categories (EPA Categories I, II, III; GHS Categories 1, 2A, 2B; EU R41, R36; FHSA Irritant) as defined by the EPA (2003a), GHS (UN 2007), EU (2001), and FHSA (2005) classification systems. Analyses were also performed excluding specific chemical classes and/or physical properties that were previously identified as discordant in the BCOP test method (alcohols, ketones, and solids) relative to the *in vivo* hazard classification (ICCVAM 2006a).

As shown in **Table 2**, overall accuracy ranged from 64% (76/118) to 83% (148/179, 155/187, and 161/194), depending on the hazard classification system used. The lowest false negative rate (0% [0/97 and 0/54]) was noted for the GHS and EU classification systems, followed by 5% (8/147 and 6/132) for FHSA-20% and FHSA-67% criteria, and 6% (8/142) for the EPA classification system. Among the eight false negatives for the EPA classification system, all were EPA Category III substances based on Draize rabbit eye test data. For the FHSA-20% and FHSA-67% criteria, eight and six substances were false negatives, respectively. The lowest false positive rate (53% [24/45, 25/47, and 25/47]) was noted for the EPA, FHSA-20%, and FHSA-67% classification systems, followed by 66% (42/64) for the EU classification system, and 70% (63/90) for the GHS classification system. The exclusion of discordant classes had a minor effect or no effect on accuracy (ranged from 60% (39/65) to 82% (53/65) when discordant classes were removed versus 64% (76/118) to 83% (148/179, 155/187, and 161/194) for overall accuracy, depending on the hazard classification system used.

BCOP Test Method Reliability

Interlaboratory Reproducibility

Previous quantitative and qualitative evaluations of the reliability of the BCOP test method have been conducted (ICCVAM 2006a). Additional qualitative analyses of interlaboratory reproducibility were conducted to evaluate how well the BCOP hazard classifications agreed among the participating laboratories from the three different interlaboratory validation studies (Balls et al. 1995; Gautheron et al. 1994; Southee 1998). These evaluations were based on the use of the BCOP test method (1) to identify all ocular hazard categories according to the EPA, EU, or GHS systems, and (2) to distinguish substances not labeled as irritants (EPA Category IV, GHS Not Classified, EU Not Labeled) from all other ocular hazard categories (EPA Categories I, II, III; GHS Categories 1, 2A, 2B; EU R41, R36). Because the performance of the BCOP test method was similar for the EPA and FHSA hazard classification systems, additional reliability analyses were not conducted for the FHSA hazard classification system.

Table 1 Evaluation of the Performance of the BCOP Test Method in Predicting Ocular Irritant Classes Compared to the *In Vivo* Rabbit Eye Test Method, as Defined by GHS, EPA, and EU Classification Systems[1]

Severe using IVIS ≥55.1											
Hazard Classification System	**Overall Correct Classification**	**Severe[2]**		**Moderate[3]**			**Mild[4]**			**Not Labeled[5]**	
		Actual	**Under**	**Over**	**Actual**	**Under**	**Over**	**Actual**	**Under**	**Over**	**Actual**
Severe using IVIS ≥ 55.1 (ICCVAM BCOP BRD [2006a])											
GHS	49% (91/187)	85% (55/65)	15% (10/65)	62% (16/26)	27% (7/26)	11% (3/26)	67% (4/6)	33% (2/6)	0% (0/6)	70% (63/90)	30% (27/90)
EPA	55% (102/187)	84% (53/63)	16% (10/63)	50% (11/22)	32% (7/22)	18% (4/22)	50% (28/57)	36% (21/57)	14% (8/57)	53% (24/45)	47% (21/45)

Without Alcohols, Ketones, and Solids	120	80	96/120	99	83/84	36	13/36	64	23/36	1	1/84

Abbreviations: BCOP = bovine corneal opacity and permeability; EPA = U.S. Environmental Protection Agency; EU = European Union; FHSA = Federal Hazardous Substances Act; GHS = Globally Harmonized System; N = number of substances included in this analysis; No. = data used to calculate the percentage.

[1] GHS classification system (UN 2007): Not Classified vs. Category 1/2A/2B.

[2] Alcohols, ketones, and solids were previously identified as discordant in the BCOP test method relative to the *in vivo* hazard classification (ICCVAM 2006a).

[3] EPA classification system (EPA 2003a): Category IV vs. Category I/II/III.

[4] EU classification system (EU 2001): Not Labeled vs. R41/R36.

[5] FHSA classification system (FHSA 2005): Not Labeled vs. Irritant. To maximize the number of substances included in the FHSA analyses, "proportionality" criteria (FHSA-20% and FHSA-67%) were applied for the purpose of assigning a FHSA classification to test results that would require additional testing according to the FHSA sequential testing strategy.

Using the first approach (identifying all ocular hazard categories) among the three interlaboratory studies for the Balls et al. (1995) study, there was 100% agreement among the five laboratories for a majority of the Draize ocular corrosives and severe irritants based on all three classification systems, whether they were correctly identified or underclassified by the BCOP test method. For example, for the GHS system, there was 100% agreement for 88% [15/17] of the correctly identified Category I substances. There was also 100% agreement among the five laboratories for 100% (10/10) of the overpredicted Not Labeled substances and for at least 50% (2/4) of the correctly identified Not Labeled substances.

For the Gautheron et al. (1994) study, there was 100% agreement among the 11 laboratories for a majority of the Draize ocular corrosives and severe irritants based on all three classification systems, whether they were correctly identified or underclassified by the BCOP test method. For example, for the GHS system, there was 100% agreement for 67% [4/6] of the correctly identified Category I substances. There was also 100% agreement among the 11 laboratories for a majority of the overpredicted Not Labeled substances (for example, for the EU system, there was 100% agreement for 54% [7/13] of the correctly identified Not Labeled substances) and for a majority of the incorrectly identified Not Labeled substances (for example, for the EU system, there was 100% agreement for 91% [21/23] of the correctly identified substances).

For the Southee (1998) study, there was 100% agreement among the three laboratories for all of the ocular corrosives and severe irritants based on all three classification systems, whether they were correctly identified or underclassified by the BCOP test method. For example, for the GHS system, there was 100% agreement for 100% [4/4] of the Draize ocular corrosives and severe irritants. There was also 100% agreement among the two correctly identified Not Labeled substances.

Using the second approach (distinguishing substances not labeled as irritants from all other ocular hazard categories) for the Balls et al. (1995) study, there was 100% agreement for 92% (55/60) to 93% (56/60) of the substances tested by the BCOP test method, depending on the classification system used. All five laboratories were in 100% agreement on the classification of 50% (2/4) of Not Labeled substances and 94% (32/34) to 96% (48/50) of all other irritant class substances, depending on the classification system used.

For the Gautheron et al. (1994) study, there was 100% agreement among the eleven laboratories for 65% (34/52) of the substances tested by the BCOP test method, for all classification systems. There was 100% agreement among the laboratories on the classification of 83% (10/12) to 87% (27/31) of all other irritant class substances, depending on the classification system used.

There was 100% agreement among the three laboratories in the Southee (1998) study for 88% (14/16) of the substances tested by the BCOP test method, for all classification systems. All three laboratories were in 100% agreement on the classification of 100% (2/2) Not Labeled substances and 90% (9/10) to 92% (11/12) of all other irritant class substances, depending on the classification system used.

1.0 Introduction

1.1 Background

The current Draize rabbit eye test method identifies both irreversible (i.e., corrosive) and reversible ocular effects. It also provides quantitative scoring with which to categorize the severity of reversible effects such as mild, moderate, or severe irritation. The current U.S. Environmental Protection Agency health effects test guideline for acute eye irritation (EPA 1998) and United Nations Globally Harmonized System (GHS) of Classification and Labelling of Chemicals (UN ocular testing strategy) indicate that if serious ocular damage is anticipated (e.g., a lesion considered to be irreversible or persisting for 21 days), then a test on a single animal may be considered. If serious damage is observed, no further animal testing is necessary (EPA 1998; UN 2007). If no serious damage is observed, additional test animals (1 or 2 rabbits) may be evaluated sequentially until concordant irritant or nonirritant responses are observed based on the GHS (UN 2007) or until unequivocal results are obtained in a minimum of three animals according to the EPA test guideline (EPA 1998). In the U.S. Federal Hazardous Substances Act (FHSA) classification system (FHSA 2005), which is based on the testing guidelines and associated criteria included in 16 CFR 1500.42 (CPSC 2003), corrosive substances are identified by other test methods (e.g., Draize skin test or human accidental exposure data) and excluded from further irritant testing.

In 2006, the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) completed an evaluation of the bovine corneal opacity and permeability (BCOP) test method for its ability to identify ocular corrosives and severe irritants (ICCVAM 2006a). ICCVAM concluded that the BCOP test method could be used, in appropriate circumstances and with certain limitations, as a screening test to identify substances as ocular corrosives and severe irritants (i.e., EPA Category I, European Union [EU] R41, GHS Category 1) (ICCVAM 2006b). While it was not considered valid as a complete replacement for the *in vivo* rabbit eye test, the BCOP test method was recommended for use as part of a tiered-testing strategy for regulatory classification and labeling within a specific applicability domain. Accordingly, substances that are positive in this test method can be classified as ocular corrosives or severe irritants without further testing in rabbits, while a substance that tests negative would need additional testing in rabbits using a sequential testing strategy as outlined in Organisation for Economic Co-operation and Development Test Guideline 405 (OECD 2002).

ICCVAM is now evaluating the usefulness and limitations of the BCOP test method for identifying nonsevere irritants (i.e., those that induce reversible ocular damage [EPA Category II and III; EU R36; GHS Category 2A and 2B]) and substances not labeled as irritants (i.e., EPA Category IV; EU Not Labeled; FHSA Not Labeled; GHS Not Classified) according to the EPA, EU, FHSA, and GHS classification systems (EPA 2003a; EU 2001; FHSA 2005; UN 2007). However, because the FHSA classification system (2005) is based on a sequential testing strategy which uses up to 18 animals, only a small percentage of the substances in the BCOP database would be classifiable if the FHSA criteria were strictly applied. In order to maximize the number of substances included in these analyses, ”proportionality“ criteria (i.e., FHSA-20% and FHSA-67%) were applied for the purpose of assigning a FHSA classification for test results that would require additional testing according to the FHSA sequential testing strategy (see **Section 4.1**).

As part of the evaluation process, this background review document (BRD) has been prepared to describe the current validation status of the BCOP test method, including what is known about its reliability and accuracy, its applicability domain, the numbers and types of substances tested, and the availability of a standardized protocol. An ICCVAM expert panel used this BRD when reviewing the BCOP as a method to identify all categories of ocular irritants and substances not labeled as irritants.

Parallel reviews of the isolated rabbit eye (IRE), hen’s egg test–chorioallantoic membrane (HET-CAM), and isolated chicken eye (ICE) test methods are being conducted. The expert panel report and the

analyses presented in the BRDs will be used to support ICCVAM recommendations on the proposed standardized test method protocols, proposed list of recommended reference substances, and additional optimization and/or validation studies that may be necessary to further develop and characterize the usefulness and limitations of these methods.

For a more detailed discussion of the background of the BCOP test method, including its scientific basis and regulatory rationale and applicability, see the ICCVAM *Background Review Document—Current Status of In Vitro Test Methods for Identifying Ocular Corrosives and Severe Irritants: Bovine Corneal Opacity and Permeability* (ICCVAM 2006a).

1.2 Use of the BCOP Test Method in Overall Strategy of Hazard or Safety Assessment

As shown in **Figure 1-1**, the GHS allows for the use of validated and accepted *in vitro* methods to identify corrosive/severe ocular irritants and ocular irritants without further testing. The BCOP test method is currently recommended for use in identifying ocular corrosives and severe irritants in a tiered-testing strategy for regulatory classification and labeling (e.g., GHS, UN 2007). ICCVAM is now further evaluating the usefulness and limitations of the BCOP test method for identifying nonsevere irritants and substances not labeled as irritants.

1.3 Validation of the BCOP Test Method

The ICCVAM Authorization Act of 2000 (Sec. 4) mandates that "each Federal Agency … shall ensure that any new or revised … test method … is determined to be valid for its proposed use prior to requiring, recommending, or encouraging [its use]" (Public Law 106-545).

Validation is the process that establishes the reliability and relevance of a test method for a specific purpose (ICCVAM 2003). *Relevance* is defined as the extent to which a test method will correctly predict or measure the biological effect of interest (ICCVAM 2003). For the BCOP test method described in the BCOP BRD (ICCVAM 2006a), relevance is restricted to how well the test method identifies substances that are capable of producing corrosive or severe irritant effects on the eye. For the current BRD, relevance is based on how well the test method identifies (1) substances that are capable of producing nonsevere ocular irritation or (2) substances not labeled as irritants.

Reliability is defined as the reproducibility of a test method within and among laboratories. Reliability should be based on performance with a diverse set of substances that represent the types of chemical and product classes likely to be tested and that cover the range of responses that need to be identified. The validation process will provide data and information to allow U.S. Federal agencies to develop guidance on the development and use of the BCOP test method as part of a tiered-testing approach to evaluating substances' eye irritation potential.

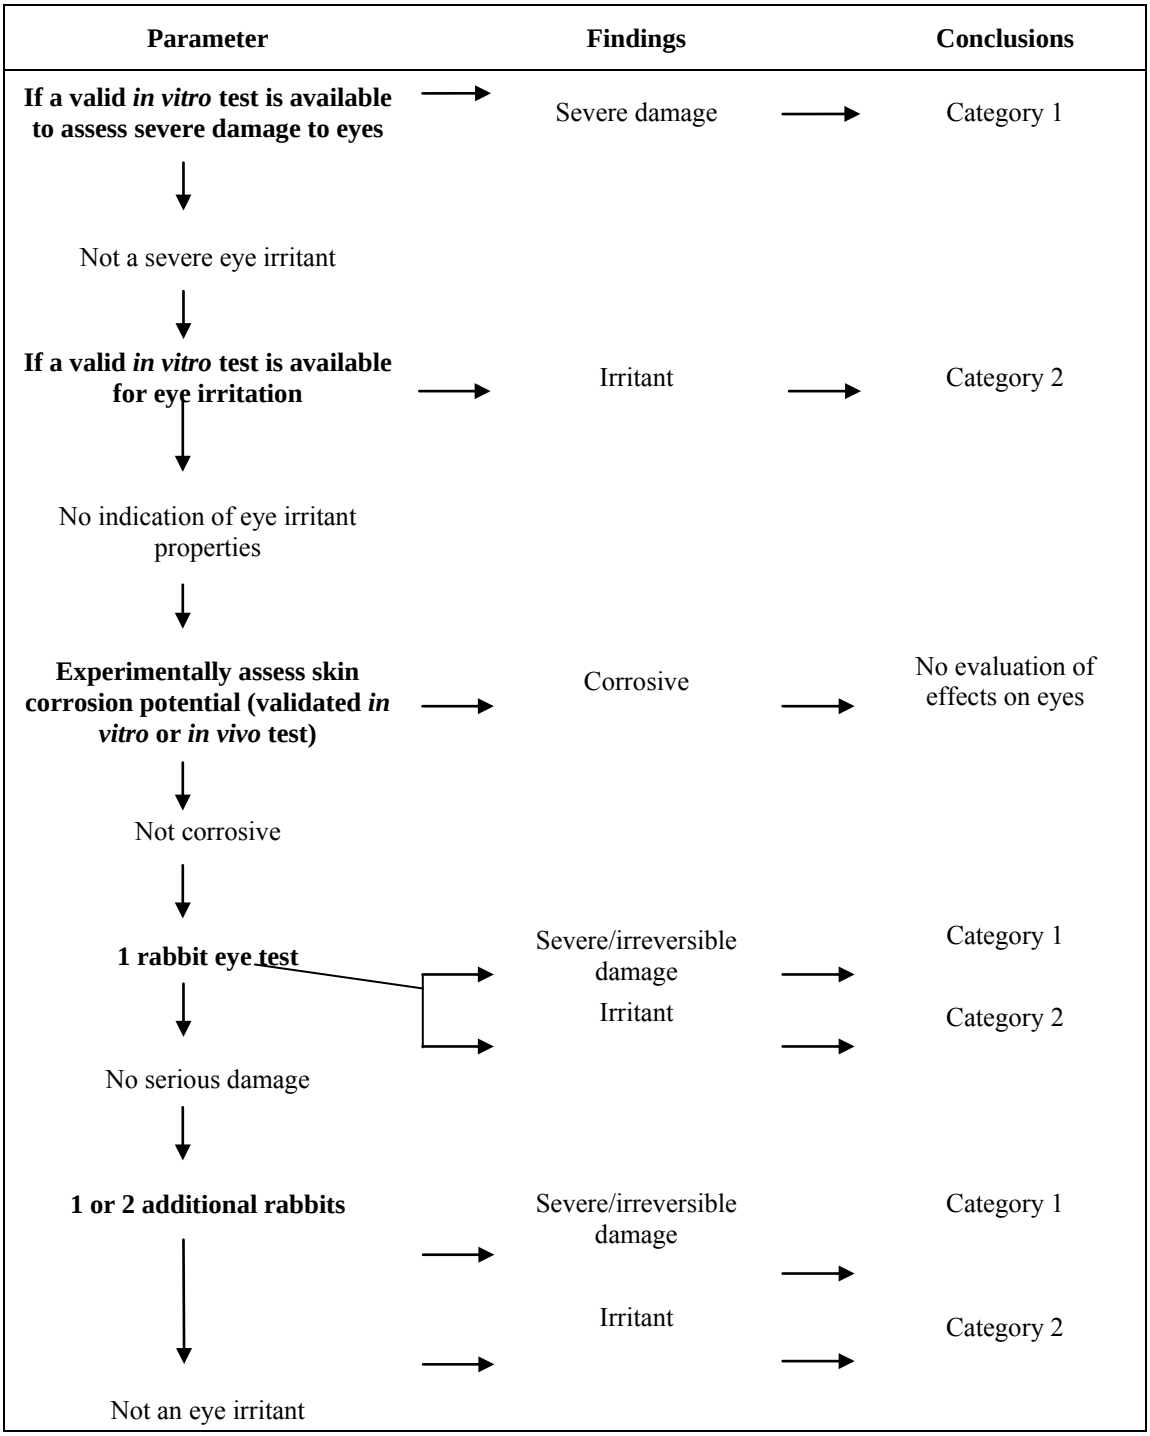
The first stage in this validation process is the preparation of a BRD that presents and evaluates the relevant data and information about the test method, including its mechanistic basis, proposed uses, reliability, and performance characteristics (ICCVAM 2003). This BRD summarizes the available information on the BCOP test method. Where adequate data is available, the qualitative and quantitative performance of the test method is evaluated.

1.4 Search Strategies and Selection of Citations for the BCOP BRD

The BCOP test method data summarized in this BRD are based on information found in the peer-reviewed scientific literature as detailed in the *Background Review Document—Current Status of In Vitro Test Methods for Identifying Ocular Corrosives and Severe Irritants: Bovine Corneal Opacity and Permeability Test Method* (ICCVAM 2006a). The National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods (NICEATM) is currently evaluating a non-animal approach for assessing eye irritation potential and labeling requirements for antimicrobial cleaning

products (AMCPs). Three *in vitro* test methods, including the BCOP, are proposed in the testing strategy. The Institute for In Vitro Sciences gave the final AMCP BRD to NICEATM on July 21, 2008. Those substances in the AMCP validation database that had been tested in the BCOP test method were added to the BCOP validation database (ICCVAM 2006a). A subsequent literature search conducted in January 2009 revealed no new articles containing BCOP test method results.

Figure 1-1 GHS Testing Strategy for Serious Eye Damage and Eye Irritation



Adapted from UN (2007).

2.0 Bovine Corneal Opacity and Permeability Test Method Protocol Components

2.1 Overview of How the BCOP Test Method is Conducted

The BCOP test method is an *in vitro* model that provides short-term maintenance of the physiological and biochemical function of the bovine cornea. In this test method, damage by the test substance is assessed by quantitative measurements of changes in corneal opacity and permeability with an opacitometer and a visible light spectrophotometer, respectively. Both measurements are used to calculate an *in vitro* irritancy score (IVIS), which is used to assign an *in vitro* irritancy hazard classification category for prediction of the *in vivo* ocular irritation potential of a test substance.

For a detailed description of how the BCOP test method is conducted, see the *Background Review Document—Current Status of In Vitro Test Methods for Identifying Ocular Corrosives and Severe Irritants: Bovine Corneal Opacity and Permeability Test Method* (ICCVAM 2006a). Briefly, isolated corneas are obtained from the eyes of freshly slaughtered cattle. Test substances are applied to the epithelial surface of the cornea using different treatment methods depending on the physical nature and chemical characteristics (e.g., solids, semisolids [including creams and waxes], liquids, viscous [including gels] vs. nonviscous liquids) of the test substance. Liquids are tested undiluted, while surfactants are tested at a concentration of 10% in a 0.9% sodium chloride solution, distilled water, or other solvent demonstrated to have no adverse effects on the test system. Corneas are exposed to liquids and surfactants for 10 minutes. Nonsurfactant solids are typically tested as solutions or suspensions at a 20% concentration in a 0.9% sodium chloride solution, distilled water, or other solvent demonstrated to have no adverse effects on the test system. Solids may also be tested neat by direct application to the corneal surface. Corneas are exposed to solids for 4 hours.

Corneal opacity is quantified as the amount of light passing through the cornea, resulting in opacity values measured on a continuous scale. Permeability is quantified as the amount of sodium fluorescein dye that passes across the full thickness of the cornea, as detected in the posterior chamber medium. The mean opacity and mean permeability (OD_{490}) values for each treatment group are then used to calculate an *in vitro* score for each treatment group:

In vitro irritancy score = mean opacity value + (15 x mean OD490 value)

The *in vitro* irritation classification schemes used for this evaluation were based on two different predetermined ranges of *in vitro* scores. The differences between the two ranges are attributed to two different criteria used to identify ocular corrosives and severe irritants (i.e., EPA Category I, GHS Category 1, EU R41). One approach (**Table 2-1**) included the ICCVAM-recommended decision criteria for identifying an ocular corrosive/severe irritant (i.e., IVIS ≥ 55.1, ICCVAM 2006b).

Table 2-1 *In Vitro* Ocular Irritancy Classification Scheme for the BCOP Test Method (ICCVAM 2006b)

***In Vitro* Score Range**	***In Vitro* Classification**
0–3.0	Not Labeled
3.1–25	Mild Irritant
25.1–55	Moderate Irritant
≥55.1	Severe Irritant

The second approach (**Table 2-2**) included an alternative decision criterion for identifying an ocular corrosive/severe irritant in the AMCP BRD (2008) submission (i.e., IVIS ≥ 75).

Table 2-2 *In Vitro* Ocular Irritancy Classification Scheme for the BCOP Test Method (AMCP BRD 2008 Submission)

***In Vitro* Score Range**	***In Vitro* Classification**
0–3.0	Not Labeled
3.1–25	Mild Irritant
25.1–74.9	Moderate Irritant
≥75	Severe Irritant

For the purposes of this evaluation, Nonirritant = EPA Category IV, GHS Not Classified, EU Not Labeled, FHSA Not Labeled; Mild Irritant = EPA Category III, GHS Category 2B; Moderate Irritant = EPA Category II, GHS Category 2A; Severe Irritant = EPA Category I, GHS Category 1, EU Category R41. The Mild and Moderate Irritant categories were combined to generate EU Category R36. The Mild, Moderate, and Severe Irritant categories were combined to generate FHSA Irritant.

For this BRD, the *in vitro* classification was compared to the corresponding *in vivo* classification for each of the EPA, GHS, and EU classification systems (EPA 2003a; UN 2007; EU 2001). For the FHSA classification system, the *in vivo* classification was compared to the *in vitro* classification based on the EPA classification system. *In vitro* classifications of Mild, Moderate, and Severe Irritant were classified as FHSA Irritant and Nonirritant was classified as FHSA Not Labeled.

3.0 Substances Used for Validation of the Bovine Corneal Opacity and Permeability Test Method

In vitro ocular test method validation studies should evaluate an adequate sample of test substances and products from chemical and product classes that have also been evaluated using the *in vivo* rabbit eye test method. Test substances with a wide range of *in vivo* ocular responses (corrosive/severe irritant to Not Labeled) also should be assessed to determine limits to the range of responses that can be evaluated by the *in vitro* test method.

The substances tested in the BCOP test method and included in the AMCP BRD were added to BCOP data employed in the ICCVAM evaluation of the BCOP for identifying ocular corrosives and severe irritants (ICCVAM 2006a). Thus, the database in the current evaluation comprises substances from the AMCP BRD along with previously evaluated published reports (Bailey et al. 2004; Balls et al. 1995; Gautheron et al. 1994; Southee 1998; Swanson et al. 1995; Swanson and Harbell 2000).

Tables 3-1 and **3-2** show the chemical and product classes for the test substances included in the database. Information, including substance name, Chemical Abstracts Service Registry Number (CASRN), chemical and/or product class, concentration(s) tested, purity, supplier or source, and literature reference using the test substance are provided in **Annex I**. If not assigned in the study report, the product class was sought from other sources, including the National Library of Medicine's ChemIDplus® database. Chemical classes were assigned to each test substance using a standard classification scheme based on the National Library of Medicine Medical Subject Headings (MeSH®) classification system (available at http//www.nlm.nih.gov/mesh) that ensures consistency in classifying substances among all *in vitro* ocular test methods under consideration. A substance could be classified in more than one chemical or product class.

As shown in **Table 3-1**, the chemical classes with the greatest amount of *in vitro* BCOP data are alcohols, carboxylic acids, esters, formulations, heterocyclic compounds, hydrocarbons, ketones, and onium compounds. Other chemical classes tested include amines, ethers/polyethers, inorganic and organic salts, and organic sulfur compounds. The formulations tested include hair shampoos, personal care cleansers, detergents, bleaches, insect repellents, petroleum products, and fabric softeners.

As shown in **Table 3-2**, the product classes tested most often in the BCOP test method are AMCPs, chemical/synthetic intermediates, cleaners, drugs/pharmaceuticals/therapeutic agents, petroleum products, shampoos, solvents, and surfactants. Other product classes tested include detergents, insect repellents, lubricants, personal care cleansers, pesticides, and plasticizers.

Table 3-1 Chemical Classes Tested in the BCOP Test Method

Chemical Class	# of Substances	Chemical Class	# of Substances
Acyl halide	3	Imide	2
Alcohol	22	Inorganic salt	6
Aldehyde	1	Ketone	12
Alkali	3	Lactone	3
Aluminum compound	1	Nitrile compound	1
Amide	2	Nitro compound	2
Amidine	6	Oil	1
Amine	10	Onium compound	12
Amino acid	4	Organic salt	3
Boron compound	1	Organic sulfur compound	5
Carboxylic acid	17	Organophosphate	1
Ester	12	Organosilicon compound	1
Ether/Polyether	9	Phenol	1
Formulation	69	Polycyclic compound	3
Heterocyclic compound	12	Terpene	1
Hydrocarbon	18	Wax	1

Table 3-2 Product Classes Tested in the BCOP Test Method

Product Class	# of Substances	Product Class	# of Substances
Adhesive	1	Fertilizer	1
Agricultural chemical	2	Flame retardant	1
Antifreeze agent	1	Flavor ingredient	3
Antimicrobial cleaning product	66	Food additive	1
Bactericide/Fungicide/ Disinfectant/Germicide	11	Herbicide	3
Beverage	1	Insect repellant	8
Bleach	3	Lubricant/lubricant additive	6
Chelating agent	2	Paint, lacquer, varnish (component)	1
Chemical/synthetic intermediate	28	Pesticide	8
Cleaner	15	Petroleum product	16
Cleanser (personal care)	13	Photographic chemical/ developing agent	2
Coupling agent	1	Plant growth regulator	2
Cutting fluid	2	Plasticizer	4
Degreaser	1	Preservative	2
Dessicant	1	Reagent	5
Detergent	11	Shampoo (hair)	14
Drug/Pharmaceutical/ Therapeutic agent and/or metabolite	17	Soap	3
Dry cleaning preparation	1	Solvent	34
Dye, in manufacture of	3	Surfactant	39
Emulsifier	1	Anionic surfactant	3
Etching and/or electroplating	2	Cationic surfactant	6
Explosive	1	Nonionic surfactant	5
Fabric softener	1	Thermometer fluid	1

4.0 *In Vivo* Reference Data Used for an Assessment of Test Method Accuracy

The Draize rabbit eye test protocol used to generate the *in vivo* reference data is detailed in the ICCVAM *Test Method Evaluation Report: In Vitro Ocular Toxicity Methods for Identifying Severe Irritants and Corrosives* (2006b). A number of national and international test guidelines also describe this procedure (CPSC 2003; EPA 1998; EU 2004; OECD 2002). The subjective scoring system used to assign an ocular hazard classification is based on a discrete scale for grading the severity of ocular lesions on the cornea, iris, and conjunctiva.

Most of the BCOP studies evaluated in this BRD include *in vivo* reference data generated using the basic procedures for the Draize rabbit eye test method. NICEATM used these data to assign an ocular hazard classification according to the EPA (2003a), EU (2001), FHSA (2005), and the GHS (UN 2007) ocular irritancy classification systems (**Annex III**). Exceptions included the following:

For Gautheron et al. (1994), the *in vivo* reference data were obtained from concurrent *in vivo* studies performed by Dr. J. Giroux at the Agence du Medicament in Montpelier, France. Studies were performed according to European Economic Committee (EEC) (1984 and 1991) guidelines with a few modifications. Three rabbits were used per test substance, and a maximum average score (MAS) (Draize et al. 1944) was calculated. Only the MAS and Day 1 scores for the 52 compounds are presented in the Gautheron et al. publication. The substances were classified by the study authors according to both EEC (1984) and Kay and Calandra (1962) systems. Detailed *in vivo* data consisting of cornea, iris, and conjunctiva scores for each animal were provided by Dr. Philippe Vanparys in January 2005. Sufficient *in vivo* data were provided to allow 48 to 52 of these substances to be classified by NICEATM according to the EPA (EPA 2003a), EU (EU 2001) FHSA (2005), and GHS (UN 2007) ocular irritancy classification systems (**Annex III**).

For the European Commission/British Home Office validation study (Balls et al. 1995), modified maximum average scores (MMASs) were calculated for the 59 test substances from existing and concurrently run *in vivo* studies, all of which were performed according to OECD Test Guideline 405 and Good Laboratory Practices (GLP) guidelines. The data were generated since 1981 and met the following criteria:

- At least 3 New Zealand White rabbits were normally tested at the same time.
- A volume of 0.1 mL or the equivalent weight of substance was instilled into the conjunctival sac.
- Anesthesia was not used.
- Observations were made at least at 1, 2, and 3 days after instillation.

All 59 of these substances were classified by NICEATM according to the EU (2001) classification system, but due to lack of sufficient *in vivo* data, only 52, 55, 57, and 58 substances, respectively, were classified according to the FHSA-67% (2005), EPA (2003a), GHS (UN 2007), and the FHSA-20% ocular irritancy classification systems (**Annex III**).

For the Swanson et al. (1995) study, *in vivo* reference data were obtained from standard (100 µL of test material; 7 formulations) or modified (30 µL of test material; 13 formulations) Draize rabbit eye tests. An MAS(30) or an MAS(100) was reported for each test substance. *In vivo* categories reported in the publication are mild (2 substances), mild/moderate (2), moderate (4), moderate/severe (1), severe/corrosive (4), and corrosive (7). These categories are based on an internal classification scheme used at S.C. Johnson & Son, Inc. After publication of the study, the sponsor, S.C. Johnson & Son, Inc., assigned EPA (2003a) and GHS (UN 2007) classifications to the substances. The sponsor provided these classifications, along with detailed *in vivo* data for each test substance, to NICEATM. NICEATM verified the EPA and GHS ocular irritancy classifications for 13 of the substances and classified the

same 13 test substances based on the EU (2001) and FHSA (2005) ocular irritancy classification systems (**Annex III**). However, 11 of the test substances evaluated using a 30 µL test substance volume were not included in the accuracy analysis, because definitive classifications could not be assigned for the four regulatory ocular irritancy classification systems.

For the European Community prevalidation study of the BCOP test method (Southee 1998), cornea, iris, and conjunctiva scores for each animal for all substances were available in the European Centre for Ecotoxicology and Toxicology of Chemicals (ECETOC) Reference Chemicals data bank (ECETOC 1998). Fifteen of the substances have been classified by NICEATM according to the EU (2001) and FHSA-20% (2005) systems; 14 of the substances were classified according to the EPA (2003a, GHS (UN 2007) and the FHSA-67% (2005) ocular irritancy classification systems (**Annex III**).

S.C. Johnson and Son, Inc., provided detailed *in vivo* reference data for 9 of the 13 test substances evaluated in the Swanson and Harbell (2000) study of ethanol-containing insect repellent formulations. The standard Draize rabbit eye test protocol was used for these nine test substances. Each test included six animals.

ExxonMobil Biomedical Sciences, Inc., provided detailed *in vivo* reference data for the 16 petrochemical products evaluated by Bailey et al. (2004). All 16 substances had been tested previously using the standard Draize rabbit eye test protocol. Each test included either three or six animals.

4.1 *In Vivo* Classification Criteria Used for BRD Analysis

As described in the ICCVAM *Background Review Document—Current Status of In Vitro Test Methods for Identifying Ocular Corrosives and Severe Irritants: Bovine Corneal Opacity and Permeability Test Method* (2006a), the *in vivo* rabbit eye test database used to analyze the accuracy of the BCOP test method includes studies that were conducted using one to six rabbits. However, some of the *in vivo* classification systems considered for the accuracy analyses are designed to be applied to studies using no more than three rabbits. Thus, to maximize the amount of data used for the evaluation of the BCOP test method, the decision criteria for each classification system were expanded to include studies that used more than three rabbits. The criteria used for classification according to the EPA (2003a), EU (2001), and GHS (UN 2007) classification systems were detailed in the 2006 ICCVAM BRD. Each of these classification systems requires that the Draize scoring system be used. For these classification systems, scoring continues until the effect is cleared, but usually not beyond 21 days after the substance is applied to the eye of the rabbit. In order for a substance to have been included in the accuracy evaluations in the 2006 ICCVAM BRD, the following four criteria must have been met.

At least three rabbits were tested in the study unless a severe effect (e.g., corrosion of the cornea) was noted in a single rabbit. In such cases, substance classification could proceed based on the effects observed in less than three rabbits.

A volume of 0.1 mL or 0.1 g was tested in each rabbit. A study in which a lower quantity was applied to the eye was accepted for substance classification provided that a severe effect (e.g., corrosion of the cornea, lesion persistence) was observed in a rabbit.

Observations of the eye were made at least 24, 48, and 72 hours after test substance application if no severe effect was observed.

Observations of the eye were made until reversibility was assessed, typically meaning that all endpoint scores were cleared. Results from a study terminated early were not used unless the reason for the early termination was documented.

If any of the above criteria were not fulfilled, then the data for that substance were omitted from the accuracy analyses. The rules used for classification according to the EPA, EU, or GHS classification systems are detailed in the ICCVAM *Background Review Document—Current Status of In Vitro Test*

Methods for Identifying Ocular Corrosives and Severe Irritants: Bovine Corneal Opacity and Permeability Test Method (2006a).

For the FHSA classification system (FHSA 2005), the testing guidelines and associated criteria are included in 16 CFR 1500.42 (CPSC 2003). The FHSA classification system is based on using up to three sequential tests for each test substance with six animals used per test (**Table 4-1**). Decisions on further sequential testing are based on the number of positive responses in each test. The severity of effects for each endpoint (i.e., corneal ulceration and opacity, conjunctival redness and/or swelling, and iritis) is measured at 24, 48, and 72 hr following test substance administration. Positive responses include corneal ulceration (other than a fine stippling), corneal opacity or iritis ≥1, and conjunctival swelling and/or redness ≥2. In the first test, six animals are tested. If ≥4 animals are positive, the test is positive. If ≤1 animal tests positive, the test is negative. If 2/6 or 3/6 animals are positive, then a second test is performed with six additional animals. A third test is needed if 1/6 or 2/6 animals are positive with the second test.

The FHSA classification system (FHSA 2005) is a binary system, which classifies substances that test positive (according to the criteria provided in **Table 4-1)** as an irritant and substances that test negative as not requiring labeling (i.e. FHSA Not Labeled). Based on the FHSA sequential testing strategy, a substance can be classified as an eye irritant hazard with a few as 22% of the animals having a positive response (i.e., 2/6 [first test] +1/6 [second test] +1/6 [third test] = 4/18 or 22%).

Because the FHSA classification system is based on a sequential testing strategy, which uses up to 18 animals, only a small percentage of the substances in BCOP database would be classifiable if the FHSA criteria were strictly applied. In order to maximize the number of substances include in these analyses, "proportionality" criteria were developed by NICEATM for the purpose of assigning a FHSA classification for test results that would require additional testing according to the FHSA sequential strategy (**Table 4-2**).

Table 4-1 FHSA Classification System (16 CFR 1500.42)[1,2]

Positive Response for a Single Rabbit[3] **≥1 of the following at 24, 48, and/or 72 hr**	***In Vivo* Effect**
Corneal ulceration (other than a fine stippling) Corneal opacity (CO) ≥1 Iritis (IR) ≥1 Conjuctival redness (CR) and/or chemosis (CC) ≥2	First Test – If ≥4/6 animals are positive, the test is positive. If ≤1 animal is positive, the test is negative. If 2/6 or 3/6 animals are positive, the test is repeated using a different group of six animals. Second Test – If ≥3/6 animals are positive, the test is positive. If 0/6 animals are positive, the test is negative. If 1/6 or 2/6 animals are positive, the test is repeated using a different group of six animals. Third Test – Should a third test be needed, the test is positive if ≥1/6 animals are positive. If 0/6 animals are positive, the test is negative.

Abbreviations: CC = conjunctival chemosis; CFR = Code of Federal Regulations; CO = corneal opacity; CR = conjunctival redness; FHSA = Federal Hazardous Substances Act; IR = iritis

1 For the FHSA Classification System (2005), the testing guidelines and associated criteria are included in 16 CFR 1500.42 (CPSC 2003).

2 At least three animals per test (one animal screen for corrosive/severe irritants permitted). Maximum score in any animal used for classification.

3 The following scores are considered positive: CO or IR ≥1 or CR or CC ≥2. Therefore, CO and IR scores of 0 or CR and CC scores ≤1 are considered negative.

Table 4-2 Proposed FHSA "Proportionality" Criteria

No. of Animals in Test	FHSA-20%[1]		FHSA-67%[1]		
	NL	Irritant	NL	Irritant	Further Testing Required
3	0/3	≥1 (≥33%)	0/3	≥2 (≥67%)	1/3
4	0/4	≥1 (≥25%)	0/4	≥3 (≥75%)	1/4, 2/4
5	0/5	≥1 (≥20%)	0/5	≥4 (≥80%)	1/5, 2/5, 3/5
6	0/6, 1/6	≥2 (≥33%)	0/6, 1/6	≥4 (≥67%)	2/6, 3/6

Abbreviations: CPSC = U.S. Consumer Product Safety Commission; FHSA = Federal Hazardous Substances Act; NL = not labeled; No. = number

[1] FHSA-20% and FHSA-67% analysis methods are based on the proportionality of positive animals needed to identify a substance as an irritant.

[2] For FHSA-67%, Further Testing Required refers to substances that do not meet adequate positive or negative criteria to be classified.

These "proportionality" criteria (i.e., FHSA-20% and FHSA-67%) are as follows:

- (FHSA-20%) – FHSA-20% is based on the proportion of positive animals needed to identify a substance as an irritant using the FHSA sequential testing strategy, where 20% of the animals need to demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled if ≤ 1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there were ≥1 positive animal in a 3 to 5 animal test or ≥2 positive animals in a 6 animal test.
- (FHSA-67%) – FHSA-67% is based on the proportion of positive animals needed to identify a substance as an irritant using the "first test" of the FHSA sequential testing strategy, where 67% of the animals need to demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled if ≤ 1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there were ≥2/3, 3/4, 4/5, or 4/6 positive animals. If 1/3, 1/4, 2/4, 1/5, 2/5, 3/5, 2/6, or 3/6 animals were positive, further testing would be required.

4.2 *In Vivo* Data Quality

Ideally, all data supporting the validity of a test method should be obtained and reported from studies conducted in accordance with GLP guidelines, which are nationally and internationally recognized rules designed to produce high-quality laboratory data and records (EPA 2003b, 2003c; FDA 2003; OECD 1998). To ensure the integrity, reliability, and accountability of a study, these guidelines provide an internationally standardized approach for the conduct of studies, reporting requirements, archival of study data and records, and information about the test protocol.

Although an attempt was made, original study records could not be obtained for the *in vivo* rabbit eye studies used to provide the comparative data in the published BCOP validation reports. Therefore, the extent to which they complied with GLP guidelines is based on the information provided in the reports themselves. Balls et al. (1995) and Southee (1998) explicitly state that GLP guidelines were followed. For the Bailey et al. (2004) report, approximately half of the *in vivo* studies were conducted according to GLP guidelines, while GLP compliance was not explicitly stated for the remaining substances. For Gautheron et al. (1994), the *in vivo* studies were conducted according to EEC test guidelines (1984 and 1991), predecessors of the current EU test guideline for eye irritation. However, this information alone does not give enough information about GLP compliance. For the remaining reports (Swanson et al. 1995 and Swanson and Harbell 2000), the extent of GLP compliance is not known.

5.0 Bovine Corneal Opacity and Permeability Test Method Data and Results

Eight reports, seven published and one unpublished, were obtained for this evaluation and used for an accuracy analysis. Test method data were extracted from seven publications, data submissions, or study reports, including Gautheron et al. (1994), Balls et al. (1995), Swanson et al. (1995), Southee (1998), Swanson and Harbell (2000), Bailey et al. (2004), and the AMCP BRD (2008). The data were sufficient for an accuracy analysis of the BCOP test method for the identification of all categories of ocular irritation. As detailed in **Section 6.0**, the data were evaluated collectively and on a per-study basis.

5.1 Availability of Copies of Original Data Used to Evaluate the Accuracy and Reliability

NICEATM staff made several attempts to obtain original *in vitro* and *in vivo* data from BCOP test method studies. In addition, NICEATM requested original BCOP data and *in vivo* reference data from authors of published BCOP studies. As a result of these efforts, some original BCOP test method data (i.e., corrected opacity and OD_{490} values for individual corneas) were obtained. The European Centre for the Validation of Alternative Methods (ECVAM) provided corrected opacity and OD_{490} values in a written report for 16 substances evaluated in the European Community Prevalidation Study of the BCOP (Southee 1998).

Dr. Joseph Sina also submitted corrected opacity and OD_{490} values electronically for 43 compounds; however, corresponding *in vivo* reference data was not obtained. ECVAM subsequently provided the mean opacity values, mean permeability values, and mean *in vitro* scores obtained for the 59 substances evaluated in the Balls et al. (1995) study. Dr. Freddy Van Goethem provided a summary table and individual cornea data for 52 compounds tested in the EEC validation study (Gautheron et al. 1994). S.C. Johnson & Son, Inc., provided transformed BCOP data (mean opacity, permeability, and *in vitro* scores) for the Swanson et al. (1995) and Swanson and Harbell (2000) studies. ExxonMobil Biomedical Sciences, Inc., provided detailed study reports for the Bailey et al. (2004) study.

The majority of other published BCOP reports, which are discussed in **Section 9.0**, did not contain sufficient *in vitro* or *in vivo* data with which to conduct an accuracy analysis.

5.2 Description of the Statistical Approaches Used to Evaluate the Resulting Data

The BCOP studies included in the accuracy analysis in this document (**Section 6.0**) evaluated variability in the BCOP test method by calculating the mean (± SD) for the opacity values and the OD_{490} values for each treatment group and control group. The mean opacity and mean permeability (OD_{490}) values for each treatment group were then used to calculate an *in vitro* irritancy score for each treatment group as follows:

In vitro irritancy score = mean opacity value + (15 x mean OD_{490} value)

Sina et al. (1995) reported that this formula was derived empirically during in-house and interlaboratory studies. The data generated for a series of 36 compounds in a multilaboratory study were subjected to a multivariate analysis to determine the equation of best fit between *in vivo* and *in vitro* data. Analysis performed by scientists at two separate companies generated nearly identical derived equations. The *in vitro* irritancy score provides a numerical value that can be used to compare the relative irritancy of test substances.

The accuracy analysis in this document focused on evaluating the ability of the BCOP test method to identify ocular corrosives and severe irritants as defined by the EPA (2003a), EU (2001), and GHS (UN 2007) hazard classification schemes. The decision criteria applied to *in vitro* data to classify a test substance as a severe ocular irritant or a nonsevere ocular irritant (i.e., mild irritant, moderate irritant)

and/or Not Labeled are similar for the four BCOP test method protocols (Gautheron et al. 1994; Balls et al. 1995; Southee 1998; Bailey et al. 2004). The *in vitro* irritation classification scheme used in these studies is similar to the decision criteria first proposed by Gautheron et al. (1994), for which *in vitro* irritancy categories were based on predetermined ranges of *in vitro* scores (see **Section 2.0**).

5.3 Summary of Results

Where provided, the specific information extracted for each substance included its name, CASRN (if available), the concentration tested, the available BCOP data (e.g., mean opacity value, mean OD_{490} value, standard deviation, number of replicates, mean *in vitro* score), the *in vitro* irritation classification of the test substance (based on the *in vitro* irritation classification scheme applied or noted by the study author), and the literature reference. Other supporting information, such as the source, purity, and physicochemical characteristics of the test substances, was included to the extent this information was available. If not provided, the CASRN was obtained from various sources, including the National Library of Medicine's ChemIDplus® database. Chemical and product classes were assigned based on the MeSH classification system (available at http://www.nlm.nih.gov/mesh). **Annex I** provides information on the names, synonyms, CASRNs, and chemical/product class, where available, for each substance. **Annex II** contains the *in vitro* BCOP test method data sorted by reference and alphabetically by substance name.

5.4 Use of Coded Chemicals and Compliance with GLP Guidelines

Ideally, all data supporting the validity of a test method should be obtained and reported in accordance with GLP guidelines and with the use of coded chemicals (OECD 1998; EPA 2003b, 2003c; FDA 2003). The data quality was evaluated by reviewing the methods sections in literature references and submitted reports. The quality of data presented in the reviewed literature references can be evaluated to the extent this information was provided in the published reports. Based on the available information, the reports that stated that they had followed GLP guidelines or used data obtained according to GLP guidelines were Bailey et al. (2004), Balls et al. (1995), and Southee (1998). The extent of GLP compliance for Swanson et al. (1995) and Swanson and Harbell (2000) were not known. The reports that said they used coded chemicals were Gautheron et al. (1994), Balls et al. (1995), Swanson et al. (1995), Southee (1998), Swanson and Harbell (2000), and Bailey et al. (2004).

6.0 Bovine Corneal Opacity and Permeability Test Method Accuracy

A critical component of an ICCVAM evaluation of the validation status of a test method is an assessment of the accuracy of the proposed test method when compared to the current reference test method (ICCVAM 2003). This aspect of test method performance is typically evaluated by calculating:

Accuracy (concordance): the proportion of correct outcomes (positive and negative) of a test method

Sensitivity: the proportion of all positive substances that are classified as positive

Specificity: the proportion of all negative substances that are classified as negative

Positive predictivity: the proportion of correct positive responses among substances testing positive

Negative predictivity: the proportion of correct negative responses among substances testing negative

False positive rate: the proportion of all negative substances that are falsely identified as positive

False negative rate: the proportion of all positive substances that are falsely identified as negative

ICCVAM evaluated the ability of the BCOP test method to identify all categories of ocular irritation potential as defined by the EPA (EPA 2003), GHS (UN 2007), and EU (EU 2001) classification systems. Given that the FHSA classification system is used to identify eye irritants based on incidence and does not differentiate between irreversible (i.e., corrosive or severe) and reversible (i.e., nonsevere) ocular effects based on Draize rabbit eye test results, an evaluation for all ocular hazard categories using the FHSA classification system was not possible.

Analyses were also performed with specific chemical classes and/or physical properties excluded based on their previous identification as discordant in the BCOP test method (ICCVAM 2006a). These evaluations were conducted on the overall data set by combining results from the reports indicated in **Section 5.0** then assigning an overall ocular irritancy classification for each substance (**Annexes II** and **III**). When the same substance was evaluated in multiple laboratories, an overall BCOP classification was based on the majority classification among all of the studies. When there were equal numbers of different irritancy classifications for substances (e.g., two tests classified a substance as Not Labeled as Irritant, and two tests classified a substance as a mild irritant), the more severe irritancy classification was used for the overall classification of the substance (mild irritant, in this case).

The *in vitro* irritation classification schemes used for this evaluation were based on two different predetermined ranges of *in vitro* scores. The differences between the two ranges are attributed to two different criteria used to identify ocular corrosives and severe irritants (i.e., EPA Category I, GHS Category 1, EU R41). One approach (**Table 2-1**) included the ICCVAM-recommended decision criteria for identifying an ocular corrosive/severe irritant (i.e., IVIS $\geq$ 55.1, ICCVAM 2006b). The second approach (**Table 2-2**) included an alternative decision criteria for identifying an ocular corrosive/severe irritant in the AMCP BRD (2008) submission (i.e., IVIS $\geq$75).

6.1 Ability to Distinguish Ocular Corrosives and Severe Irritants from All Other Classes

The BCOP test method has been recommended previously for use in identifying ocular corrosives and severe irritants (i.e., EPA Category I, GHS Category 1, and EU R41; ICCVAM 2006b). The original ICCVAM evaluation of the BCOP test method was based on 145 substances. Overall accuracy rates were 79% (113/143) to 81% (119/147) depending on the hazard classification system evaluation (i.e., EPA, GHS, or EU). False positive rates were 19% (20/103) to 21% (22/103), and false negative rates were 16% (7/43) to 25% (10/40), also depending on the hazard classification system.

Because additional substances with sufficient BCOP and *in vivo* data were added to the BCOP test method validation database, this evaluation was repeated to verify similar performance. Based on the

current BCOP validation database, which has increased to 211 substances, overall accuracy is 77% (91/118) to 79% (147/186) depending on the hazard classification system evaluation (i.e., EPA, GHS, or EU). The false positive rate is 23% (29/124) to 24% (29/122), and false negative rates are 15% (10/65) to 21% (7/33) depending on the hazard classification system evaluation (**Table 6-1**).

Table 6-1 Accuracy of the BCOP Test Method in Distinguishing Ocular Corrosives/Severe Irritants from All Other Categories, as Defined by the EPA, GHS, and EU Classification Systems[1]

BCOP	N	Accuracy		Sensitivity		Specificity		False Positive Rate		False Negative Rate	
		%	No.	%	No.	%	No.	%	No.	%	No.
GHS	187	79	148/187	85	55/65	76	93/122	24	29/122	15	10/65
EPA	187	79	148/187	84	53/63	77	95/124	23	29/124	16	10/63
EU	118	77	91/118	79	26/33	76	65/85	24	20/85	21	7/33

Abbreviations: BCOP= bovine corneal opacity and permeability; EPA = U.S. Environmental Protection Agency; EU = European Union; GHS = Globally Harmonized System; N = number of substances included in this analysis; No. = data used to calculate the percentage.

[1] EPA classification system (EPA 2003a); GHS classification system (UN 2007); EU classification system (EU 2001)

The following sections provide detailed analyses and results of the performance of the BCOP test method for each of the ocular hazard classification systems (i.e., EPA, GHS, and EU).

6.2 GHS Classification System: BCOP Test Method Accuracy

This accuracy evaluation used seven reports: Gautheron et al. (1994), Balls et al. (1995), Swanson et al. (1995), Southee (1998), Swanson and Harbell (2000), Bailey et al. (2004), and the AMCP BRD (2008) submission. These included BCOP data for 211 substances, 187 of which had sufficient *in vivo* data to be assigned an ocular irritancy classification according to the GHS classification system (UN 2007 (see **Annex III**). Among these studies, Gautheron et al. (1994), Balls et al. (1995), and Southee (1998) provided BCOP data for substances tested in multiple laboratories. Thus a consensus *in vitro* classification had to be assigned to each substance. Based on results from *in vivo* rabbit eye experiments, 35% (65/187) were classified as Category 1, 14% (26/187) were classified as Category 2A, 3% (6/187) were classified as Category 2B, and 48% (90/187) were classified as Not Classified as Irritant. Twenty-four substances could not be classified according to the GHS classification system due to the lack of adequate animal data.

6.2.1 Identification of Category 1 Substances (Ocular Corrosives/Severe Irritants)

The BCOP test method correctly identified 85% (55/65) and 78% (51/65) of the Category 1 substances using decision criteria of IVIS ≥55.1 and IVIS ≥75, respectively (**Table 6-2**). Among the Category 1 substances that were underpredicted by BCOP (based on IVIS ≥55.1), 9% (6/65) were classified as Category 2A, and 6% (4/65) were classified as Category 2B. Among the Category 1 substances that were underpredicted by the BCOP test method (based on IVIS ≥75), 15% (10/65) were classified as Category 2A and 6% (4/65) were classified as Category 2B.

6.2.2 Identification of Category 2A Substances (Moderate Ocular Irritants)

Of the 26 substances that could be evaluated, the BCOP test method correctly identified 27% (7/26) as moderate irritants, overpredicted 62% (16/26), and underpredicted 11% (3/26) using decision criteria defining ocular corrosives/severe irritants ≥55.1 (**Table 6-2**). Using decision criteria defining ocular

corrosives/severe irritants ≥75, the BCOP test method correctly identified 54% (14/26) as moderate irritants, overpredicted 31% (8/26), and underpredicted 15% (4/26) (**Table 6-2**).

6.2.3 Identification of Category 2B Substances (Mild Ocular Irritants)

Regardless of the decision criteria used to define ocular corrosives/severe irritants, of the six substances that could be evaluated, the BCOP test method correctly identified 33% (2/6) as mild irritants while overpredicting 67% (4/6) (**Table 6-2**).

6.2.4 Identification of Substances Not Classified as Irritant

Regardless of the decision criteria used to define ocular corrosives/severe irritants, of the 90 substances that could be evaluated, the BCOP test method correctly identified 30% (27/90) as Not Classified as Irritant while overpredicting 70% (63/90) (**Table 6-2**).

6.2.5 Overall Correct Classification

As indicated in **Table 6-2**, the use of the alternative decision criteria proposed in the AMCP BRD (2008), in which ocular corrosives/severe irritants ≥75, did not improve the overall performance of BCOP hazard classification. Therefore, the remaining analyses will present results utilizing the ICCVAM-recommended decision criteria for ocular corrosives/severe irritants (≥55.1). Overall, correct classification for the entire database of 187 substances was 49% (91/187) but ranged from 25% (2/8) to 60% (6/10 or 9/15) when each of the eight individual validation databases was evaluated (**Table 6-3**).

6.2.6 Ability to Distinguish Substances Not Classified as Irritant from All Other Classes

In addition to evaluating the ability of the BCOP test method to identify each individual ocular hazard category according to the GHS classification system, ICCVAM evaluated the ability of the BCOP test method to distinguish substances not classified as irritants from all other irritant classes. Using this approach for the 187 substances considered, the BCOP test method has an accuracy of 66% (124/187), a sensitivity of 100% (97/97), a specificity of 30% (27/90), a false positive rate of 70% (63/90) and a false negative rate of 0% (0/97) (**Table 6-4**).

As detailed below, the results from each individual study were also evaluated separately.

Gautheron et al. (1994): Based upon the *in vivo* rabbit data, 47 substances could be assigned a GHS classification. Based on these 47 substances, the BCOP test method has an accuracy of 55% (26/47), sensitivity of 100% (13/13), specificity of 38% (13/34), false positive rate of 62% (21/34), and a false negative rate of 0% (0/13) (**Table 6-4**).

Balls et al. (1995): Based upon the *in vivo* rabbit data, 54 substances could be assigned a GHS classification. Based on these 54 substances, the BCOP test method has an accuracy of 83% (45/54), sensitivity of 100% (40/40), specificity of 36% (5/14), false positive rate of 64% (9/14), and a false negative rate of 0% (0/40) (**Table 6-4**).

Swanson et al. (1995): Based upon the *in vivo* rabbit data, 10 substances could be assigned a GHS classification. Based on these 10 substances, the BCOP test method has an accuracy of 60% (6/10), sensitivity of 100% (6/6), specificity of 0% (0/4), false positive rate of 100% (4/4), and a false negative rate of 0% (0/6) (**Table 6-4**).

Table 6-2 Performance of the BCOP Test Method in Predicting Ocular Irritant Classes Compared to the *In Vivo* Rabbit Eye Test Method, as Defined by EPA, GHS, and EU Classification Systems[1]

Severe using IVIS ≥ 55.1											
	Overall Correct Classification	Severe[2]		Moderate[3]			Mild[4]			Not Labeled[5]	
		Actual	Under	Over	Actual	Under	Over	Actual	Under	Over	Actual

Abbreviations: BCOP = bovine corneal opacity and permeability; GHS = Globally Harmonized System; N = number of substances included in this analysis; No. = data used to calculate the percentage.

[1] GHS (UN 2007): NL vs. Categories 1/2A/2B.

Southee (1998): Based upon the *in vivo* rabbit data, 15 substances could be assigned a GHS classification. Based on these 15 substances, the BCOP test method has an accuracy of 93% (14/15), sensitivity of 100% (12/12), specificity of 67% (2/3), false positive rate of 33% (1/3), and a false negative rate of 0% (0/12) (**Table 6-4**).

Swanson and Harbell (2000): Based upon the *in vivo* rabbit data, eight substances could be assigned a GHS classification. Based on these eight substances, the BCOP test method has an accuracy of 63% (5/8), sensitivity of 100% (5/5), specificity of 0% (0/3), false positive rate of 100% (3/3), and a false negative rate of 0% (0/5) (**Table 6-4**).

Bailey et al. (2004): Based upon the *in vivo* rabbit data, 14 substances could be assigned a GHS classification. Based on these 14 substances, the BCOP test method has an accuracy of 57% (8/14), sensitivity of 100% (4/4), specificity of 40% (4/10), false positive rate of 60% (6/10), and a false negative rate of 0% (0/4) (**Table 6-4**).

AMCP BRD (2008): Based upon the *in vivo* rabbit data, 65 substances could be assigned a GHS classification. Based on these 65 substances, the BCOP test method has an accuracy of 63% (41/65), sensitivity of 100% (36/36), specificity of 17% (5/29), false positive rate of 83% (24/29), and a false negative rate of 0% (0/36) (**Table 6-4**).

6.2.7 Discordant Results According to the GHS Classification System

In order to evaluate BCOP test method responses that disagreed with the *in vivo* hazard classification, several accuracy subanalyses were performed. These included specific classes of chemicals and certain properties of interest considered relevant to ocular toxicity testing (e.g., surfactants, physical form) with sufficiently robust numbers of substances (n ≥5).

Table 6-5 shows some notable trends in the performance of the BCOP test method among these subgroups of substances. The chemical classes of substances that the BCOP test method most consistently overpredicted according to the GHS classification system were alcohols and hydrocarbons. Of the 53 overpredicted substances, eight were alcohols and eight were hydrocarbons. Additional chemical classes represented among the overpredicted substances were carboxylic acids (6), heterocyclic compounds (4), and esters (4). Among the 23 substances labeled as surfactants, the BCOP test method overpredicted 22% (5/23).

Forty-four of the substances overpredicted by the BCOP test method were liquids, and nine were solids. Considering the proportion of the total available database, the BCOP test method appears more likely to overpredict liquids (90/122 or 74%) than solids (32/122 or 26%).

Alcohols (2) and carboxylic acids (2) were most often underpredicted (i.e., false negatives[1]) by the BCOP test method according to the GHS classification system (see **Annex III**). As can be seen in **Table 6-5**, the 16 irritant substances labeled as surfactants were rarely underpredicted by the BCOP test method (7% [1/14] Category 1 substances was underpredicted; none of the Category 2A or 2B substances were underpredicted).

With regard to physical form, six of the substances underpredicted by the BCOP test method were liquids and five were solids. Given the proportion of the total available database, the BCOP test method appears more likely to underpredict solids (32/122 or 26%) than liquids (90/122 or 74%).

Table 6-6 shows the effects on the BCOP test method performance statistics of excluding from the data set problematic classes (i.e., those which gave the most discordant results according to the GHS classification system) identified in the BCOP BRD (ICCVAM 2006a). In general, exclusion of alcohols, ketones, or solids individually resulted in small changes in the performance statistics. Slight increases in the overall correct classification were noted with the exclusion of problematic classes, with the highest correct classification, 51% (49/97), noted when alcohols and ketones were both excluded. The exclusion of problematic classes had little impact on the ability of the BCOP test method to identify substances not labeled as irritants (see **Table 6-7**). Accuracy was 68% (83/122) with the entire database but ranged from 64% to 69% when problematic classes or combinations were excluded.

In **Table 6-5**, hydrocarbons are noted as discordant when the BCOP test method was evaluated for its ability to identify all hazard categories. Among the 11 hydrocarbons in the validation database, 73% (8/11) were overpredicted by the BCOP test method (**Table 6-5**). Compared to the entire database, exclusion of hydrocarbons resulted in only modest improvements in overall correct classification (50% [55/111] versus 48% (58/122]) and identification of Not Labeled substances (38% [19/50] versus 36% [22/61]) (**Table 6-6**). Exclusion of hydrocarbons also resulted in modest improvement in overall performance in identifying Not Labeled substances (see **Table 6-7**). Accuracy increased from 68% (83/112) to 72% (80/111). The false positive rate decreased from 64% (39/61) to 62% (31/50), while the false negative rate remained 0% (0/61 versus 0/61).

---

[1] *False negative* in this context refers to a substance that the BCOP test method classified as a nonsevere (mild or moderate) irritant or Not Labeled but that the *in vivo* data classified as a severe irritant.

[1] GHS classification system (UN 2007): NL vs. Categories 1/2A/2B.

6.3 EPA Classification System: BCOP Test Method Accuracy

The seven reports used in the accuracy evaluation (Gautheron et al. 1994; Balls et al. 1995 ; Swanson et al. 1995 ; Southee 1998; Swanson and Harbell 2000; Bailey et al. 2004; and the AMCP BRD 2008) included BCOP data on 211 substances, 187 of which had sufficient *in vivo* data to be assigned an ocular irritancy classification according to the EPA classification system (EPA 2003a) (see **Annex III**). Among these studies, Gautheron et al. (1994), Balls et al. (1995), and Southee (1998) provided BCOP data for substances tested in multiple laboratories and thus required that a consensus *in vitro* classification be assigned to each substance. Based on results from *in vivo* rabbit eye experiments, 35% (65/187) were classified as Category I, 14% (26/187) were classified as Category II, 3% (6/187) were classified as Category III, and 48% (90/187) were classified as Category IV. Twenty-four substances could not be classified according to the GHS classification system due to the lack of adequate animal data (noted in **Annex III)**.

6.3.1 Identification of Category I Substances (Ocular Corrosives/Severe Irritants)

The BCOP test method correctly identified 84% (53/63) and 78% (49/63) of the Category I substances using decision criteria defining ocular corrosives/severe irritants ≥55.1 and ocular corrosives/severe irritants ≥75, respectively (**Table 6-2**). Using decision criteria defining *in vitro* scores ≥55.1 as ocular corrosives/severe irritants, of the Category I substances that were underpredicted by the BCOP test method, 10% (6/63) were classified as Category II, and 6% (4/63) were classified as Category III. Using decision criteria defining *in vitro* scores ≥75 as ocular corrosives/severe irritants, of the Category I substances that were underpredicted by BCOP test method, 16% (10/63) were classified as Category II, and 6% (4/63) were classified as Category III.

6.3.2 Identification of Category II Substances (Moderate Ocular Irritants)

Of the 22 substances that could be evaluated, the BCOP test method correctly identified 32% (7/22) as moderate irritants, while 50% (11/22) were overpredicted and 18% (4/22) were underpredicted using decision criteria that defined *in vitro* scores ≥55.1 as ocular corrosives/severe irritants (**Table 6-8**). Using decision criteria defining *in vitro* scores ≥75 as ocular corrosives/severe irritants, the BCOP test method correctly identified 45% (10/22) as moderate irritants, while overpredicting 36% (8/22) and underpredicting 19% (4/22) (**Table 6-2**).

6.3.3 Identification of Category III Substances (Mild Ocular Irritants)

Using decision criteria defining *in vitro* scores ≥55.1 as ocular corrosives/severe irritants, for the 56 substances that could be evaluated, the BCOP test method correctly identified 36% (21/57) as mild irritants, while 50% (28/57) were overpredicted and 14% (8/57) were underpredicted (**Table 6-8**). Using decision criteria defining *in vitro* scores ≥75 as ocular corrosives/severe irritants, for the 57 substances that could be evaluated, the BCOP test method correctly identified 39% (22/57) as mild irritants, while 47% (27/57) were overpredicted and 14% (8/57) were underpredicted (**Table 6-2**).

6.3.4 Identification of Category IV Substances

Regardless of the decision criteria used to define *in vitro* scores as ocular corrosives/severe irritants, for the 45 substances that could be evaluated, the BCOP test method correctly identified 47% (21/45) as Category IV, while 53% (24/45) were overpredicted (**Tables 6-2 and 6-8**).

6.3.5 Ability to Distinguish Category IV from All Other Classes

In addition to evaluating the ability of the BCOP test method to identify each individual ocular hazard category according to the EPA classification system, ICCVAM also evaluated the ability of the BCOP

test method to distinguish Category IV from all other irritant classes. Using this approach for the 187 substances considered, the BCOP test method has an accuracy of 83% (155/187), a sensitivity of 94% (134/142), a specificity of 47% (21/45), a false positive rate of 53% (24/45), and a false negative rate of 6% (8/142) (**Table 6-9**).

As detailed below, the results from each individual study were also evaluated separately.

Gautheron et al. (1994): Based upon the *in vivo* rabbit data, 48 substances could be assigned an EPA classification. Based on these 48 substances, the BCOP test method has an accuracy of 83% (40/48), sensitivity of 89% (31/35), specificity of 69% (9/13), false positive rate of 31% (4/13), and a false negative rate of 11% (4/35) (**Table 6-9**).

Balls et al. (1995): Based upon the *in vivo* rabbit data, 54 substances could be assigned an EPA classification. Based on these 54 substances, the BCOP test method has an accuracy of 93% (50/54), sensitivity of 92% (48/52), specificity of 100% (2/2), false positive rate of 0% (0/2), and a false negative rate of 8% (4/52) (**Table 6-9**).

Swanson et al. (1995): Based upon the *in vivo* rabbit data 10 substances could be assigned an EPA classification. Based on these 10 substances, the BCOP test method has an accuracy of 90% (9/10), sensitivity of 100% (9/9), specificity of 0% (0/1), false positive rate of 100% (1/1), and a false negative rate of 0% (0/9) (**Table 6-9**).

Southee (1998): Based upon the *in vivo* rabbit data, 15 substances could be assigned an EPA classification. Based on these 15 substances, the BCOP test method has an accuracy of 93% (14/15), sensitivity of 93% (13/14), specificity of 100% (1/1), false positive rate of 0% (0/1), and a false negative rate of 7% (0/14) (**Table 6-9**).

Swanson and Harbell (2000): Based upon the *in vivo* rabbit data, eight substances could be assigned an EPA classification. Based on these eight substances, the BCOP test method has an accuracy of 75% (6/8), sensitivity of 100% (6/6), specificity of 0% (0/2), false positive rate of 100% (2/2), and a false negative rate of 0% (0/6) (**Table 6-9**).

Bailey et al. (2004): Based upon the *in vivo* rabbit data, 13 substances could be assigned an EPA classification. Based on these 13 substances, the BCOP test method has an accuracy of 62% (8/13), sensitivity of 75% (3/4), specificity of 44% (4/9), false positive rate of 56% (5/9), and a false negative rate of 25% (1/4) (**Table 6-9**).

AMCP BRD (2008): Based upon the *in vivo* rabbit data, 66 substances could be assigned an EPA classification. Based on these 66 substances, the BCOP test method has an accuracy of 79% (52/66), sensitivity of 98% (47/48), specificity of 28% (5/18), false positive rate of 72% (13/18), and a false negative rate of 2% (1/48) (**Table 6-9**).

[1] EPA classification system (EPA 2003a): Category IV vs. Categories I/II/III.

Among the eight false negatives for the EPA system, 100% (8/8) were EPA Category III substances based on Draize test data. For 38% (3/8) of these substances, the categorization was based on at least one rabbit with a corneal opacity score of 1 that was not resolved until Day 3 of the study. Another substance was categorized based on all six rabbits with a conjunctival redness score of 3 that was not resolved until Day 7 of the study. Among the seven false negative substances for which chemical class and/or physical properties could be assigned, 71% (5/7) were from discordant classes that have previously been identified for the BCOP test method (i.e., either ketones or solids; see also ICCVAM 2006a). Chemical class information was unavailable for the one substance that was from the AMCP BRD 2008 (**Table 6-10**).

Table 6-10 BCOP False Negative Substances[1]

Substance (Discordant Class Y/N)	*In Vivo* Classification					*In Vivo* Scores		
	EPA	GHS	EU	FHSA-20%	FHSA-67%	N	Corneal Opacity: Score (Day Cleared)	Conjunctival Redness: Score (Day Cleared)
Dimethylbiquanide (Y)	III	NC	NL	Irr	Irr	3	N=1 1(2) N=1 1(3)	N=2 2(3)
EDTA (Y)	III	NC	NL	Irr	Irr	3	N=1 1(3)	N=3 2(2)
Iminodibenzyl (Y)	III	NC	NL	Irr	Irr	3	N=3 1(2)	-

L-Aspartic acid (Y)	SCNM	SCNM	SCNM	Irr	Irr	3	N=1 1(3), N=1 1(>3) N=1 3(>3)	N=3 3(2)
DL-Glutamic acid (Y)	SCNM	SCNM	SCNM	Irr	FTR	3	N=1 1(2)	-

Abbreviations: BCOP = bovine corneal opacity and permeability; EPA = U.S. Environmental Protection Agency; EU = European Union; FTR = further testing required; GHS = Globally Harmonized System; Irr = irritant; N = number of animals; NC = Not Classified (as irritant); NL = Not Labeled (as irritant); SCNM = study criteria not met.

For the purposes of this evaluation, *clearing* is defined in the EPA hazard classification system as corneal opacity or iritis scores = 0 or redness or chemosis scores = 1; in the GHS and EU hazard classification systems as corneal opacity, iritis, redness, or chemosis scores = 0.

[1] False negative compounds (shaded here) are those that test as nonirritants *in vitro* but are mild, moderate, or severe ocular irritants/corrosive *in vivo*, i.e., EPA Categories I, II, and III; GHS Categories 1, 2A, and 2B; and EU R41 and R36.

6.3.6 Discordant Results According to the EPA Classification System

In order to evaluate discordant responses of the BCOP test method relative to the *in vivo* hazard classification, several accuracy subanalyses were performed. These included specific classes of chemicals with sufficiently robust numbers of substances (n ≥5), as well as certain properties of interest considered relevant to ocular toxicity testing (e.g., pesticides, surfactants, pH, physical form). **Table 6-11** shows some notable trends in the performance of the BCOP test method among these subgroups of substances. According to the EPA classification system, alcohols are the chemical class most consistently overpredicted by the BCOP test method. Nine of the 41 overpredicted substances were alcohols. Additional chemical classes represented among the overpredicted substances were hydrocarbons (6), carboxylic acids (5), ketones (4), esters (4), ethers (3), inorganic (1), and onium compounds (1). Among the substances labeled as surfactants, the BCOP test method overpredicted 32% (7/22).

Thirty-seven of the substances overpredicted by the BCOP test method were liquids and four were solids. Considering the proportion of the total available database, liquids (89/121 or 74%) appear more likely than solids (32/121 or 26%) to be overpredicted by the BCOP test method. Among the 22 substances labeled as surfactants, the BCOP test method overpredicted 32% (7/22).

According to the EPA classification system (see **Annex III**), the BCOP test method underpredicted relatively few substances (i.e., false negatives). Alcohols (2), esters (2), and heterocyclic compounds were most often underpredicted. As can be seen in **Table 6-11**, the 19 irritant substances labeled as surfactants were rarely underpredicted by the BCOP test method (9% [1/11] Category 1 substances were underpredicted; no Category II were underpredicted and 17% [1/6] Category III substances were underpredicted).

Nine of the substances underpredicted by the BCOP test method were solids, and nine were liquids. Given the proportion of the total available database, the BCOP test method appears more likely to underpredict solids (32/121 or 26%) than liquids (89/121 or 74%).

Table 6-12 shows the effects on the BCOP test method performance statistics of excluding from the data set problematic classes (i.e., those that gave the most discordant results according to the EPA classification system) identified in the BCOP BRD (ICCVAM 2006a). In general, the exclusion of alcohols, ketones, or solids individually resulted in small changes in the performance statistics. Exclusion of both alcohols and ketones improved the overall classification rate: 56% (54/96) versus 51% (62/121) for all compounds in the database. The classification of ocular corrosives/severe irritants was most improved by the exclusion of problematic classes. Using the entire database, 75% (24/32) of severe ocular corrosives/severe irritants were accurately classified. Removal of solids resulted in 86% (18/21) correct classification. Removal of alcohols, ketones, and solids resulted in correct classification of 90% (18/20) of Category I substances.

Abbreviations: BCOP = bovine corneal opacity and permeability; EPA = U.S. Environmental Protection Agency.

[1] EPA classification system (EPA 2003a).

[2] Chemical classes included in this table are represented by at least five substances tested in the BCOP test method and assignments are based upon National Library of Medicine medical subject heading (MeSH) categories (www.nlm.nih.gov/mesh) as defined in **Annex I**.

As shown in **Table 6-11**, hydrocarbons were also noted as discordant when the BCOP test method was evaluated for its ability to identify all hazard categories. Among the 11 hydrocarbons in the validation database, the BCOP test method overpredicted 55% (6/11) (**Table 6-11**). Compared to the entire database, exclusion of hydrocarbons resulted in only modest improvement in overall correct classification (52% [57/110] versus 51% [62/121]) and identification of Category IV substances (62% [13/21] versus 59% [16/27]) (**Table 6-12**). Accuracy increased from 85% (103/121) to 86% (95/110), and the false positive rate decreased from 41% (11/27) to 38% (8/21). However, exclusion of hydrocarbons slightly increased the false negative rate from 7% (7/94) to 8% (7/89).

Table 6-13 shows how the ability of the BCOP test method to distinguish Category IV substances was affected by exclusion of problematic classes from the data set. Exclusion of problematic classes individually or in combination had little effect on accuracy (85% versus 82% to 87%), sensitivity (91% to 96%), or specificity (44% to 63%). The overall false positive rate of 7% (7/94) showed the largest decrease following the exclusion of solids, the false positive rate dropping to 4% (3/69).

6.4 EU Classification System: BCOP Test Method Accuracy

The six reports used in the accuracy evaluation (Gautheron et al. 1994, Balls et al. 1995, Swanson et al. 1995, Southee 1998, Swanson and Harbell 2000, and Bailey et al. 2004) included BCOP data on 118 substances that had sufficient *in vivo* data to be assigned an ocular irritancy classification according to the EU classification system (EU 2004) (see **Annex III**). Among these studies, Gautheron et al. (1994), Balls et al. (1995), and Southee (1998) provided BCOP data for substances tested in multiple laboratories and thus required that a consensus *in vitro* classification be assigned to each substance. Based on results from *in vivo* rabbit eye experiments, 28% (33/118) were classified as R41, 14% (21/118) were classified as R36, and 54% (64/118) were classified as Not Labeled.

6.4.1 Identification of R41 Substances (Ocular Corrosives/Severe Irritants)

The BCOP test method correctly identified 79% (26/33) and 73% (24/33) of the R41 substances using decision criteria that defined *in vitro* scores ≥55.1 as R41 and *in vitro* scores ≥75 as R41, respectively (**Table 6-2**). Using decision criteria that defined *in vitro* scores ≥55.1 as R41, all seven substances that were underpredicted by the BCOP test method were classified as R36. Using decision criteria that defined *in vitro* scores ≥75 as R41, all nine substances that were underpredicted by the BCOP test method were classified as R36.

6.4.2 Identification of R36 Substances (Irritants)

For the 21 substances that could be evaluated, the BCOP test method correctly identified 52% (11/21) as R36, while 48% (10/21) were overpredicted using decision criteria defining *in vitro* scores ≥55.1 as R41 (**Table 6-14**). Using decision criteria that defined *in vitro* scores ≥75 as R41, the BCOP test method correctly identified 67% (14/21) as R36, while 29% (6/21) were overpredicted and 4% (1/21) were underpredicted (**Table 6-2**).

Table 6-12 Performance of the BCOP Test Method in Predicting Ocular Irritant Classes Compared to the *In Vivo* Rabbit Eye Test Method, as Defined by the EPA Classification System,[1] with Discordant Chemical and Physical Classes Excluded

[1] EPA classification system (EPA 2003a); Category IV vs. Categories I/II/III.

6.4.3 Identification of Not Labeled Substances

Regardless of the decision criteria used to define R41, for the 64 substances that could be evaluated, the BCOP test method correctly identified 34% (22/64) as Not Labeled, while 66% (42/64) were overpredicted (**Table 6-14**).

6.4.4 Ability to Distinguish Not Labeled Substances from All Other Classes

In addition to evaluating the ability of the BCOP test method to identify each individual ocular hazard category according to the EU classification system, ICCVAM also evaluated the ability of the BCOP test method to distinguish Not Labeled substances from all other irritant classes. Using this approach for the 118 substances considered, the BCOP test method has an accuracy of 64% (76/118), a sensitivity of 100% (54/54), a specificity of 34% (22/64), a false positive rate of 66% (42/64), and a false negative rate of 0% (0/54) (**Table 6-15**).

[1] EU classification system (EU 2001): Not Labeled vs. R41/R36.

As detailed below, the results from each individual study were also evaluated separately.

Gautheron et al. (1994): Based upon the *in vivo* rabbit data, 43 substances could be assigned EU classifications. Based on these 43 substances, the BCOP test method has an accuracy of 51% (22/43), sensitivity of 100% (12/12), specificity of 32% (10/31), false positive rate of 68% (21/31), and a false negative rate of 0% (0/12) (**Table 6-15**).

Balls et al. (1995): Based upon the *in vivo* rabbit data, 50 substances could be assigned EU classifications. Based on these 50 substances, the BCOP test method has an accuracy of 78% (39/50), sensitivity of 100% (34/34), specificity of 31% (5/16), false positive rate of 69% (11/16), and a false negative rate of 0% (0/34) (**Table 6-15**).

Swanson et al. (1995): Based upon the *in vivo* rabbit data, 12 substances could be assigned EU classifications. Based on these 12 substances, the BCOP test method has an accuracy of 50% (6/12), sensitivity of 100% (6/6), specificity of 0% (0/6), false positive rate of 100% (6/6), and a false negative rate of 0% (0/6) (**Table 6-15**).

Southee (1998): Based upon the *in vivo* rabbit data, 15 substances could be assigned EU classifications. Based on these 15 substances, the BCOP test method has an accuracy of 87% (13/15), sensitivity of 100% (11/11), specificity of 50% (2/4), false positive rate of 50% (2/4), and a false negative rate of 0% (0/11) (**Table 6-15**).

Swanson and Harbell (2000): Based upon the *in vivo* rabbit data, eight substances could be assigned EU classifications. Based on these eight substances, the BCOP test method has an accuracy of 63% (5/8), sensitivity of 100% (5/5), specificity of 0% (0/3), false positive rate of 100% (3/3), and a false negative rate of 0% (0/5) (**Table 6-15**).

Bailey et al. (2004): Based upon the *in vivo* rabbit data, 13 substances could be assigned EU classifications. Based on these 13 substances, the BCOP test method has an accuracy of 54% (7/13), sensitivity of 100% (3/3), specificity of 40% (4/10), false positive rate of 60% (6/10), and a false negative rate of 0% (0/3) (**Table 6-15**).

6.4.5 Discordant Results According to the EU Classification System

In order to evaluate discordant responses of the BCOP test method relative to the *in vivo* hazard classification, several accuracy subanalyses were performed. These included specific classes of chemicals with sufficiently robust numbers of substances (n ≥5), as well as certain properties of interest considered relevant to ocular toxicity testing (e.g., surfactants and physical form, respectively).

Table 6-16 shows some notable trends in the performance of the BCOP test method among these subgroups of substances. The chemical class of substances that was most consistently overpredicted according to the EU classification system by the BCOP test method was hydrocarbons. Seven of the 42 overpredicted substances were hydrocarbons. Additional chemical classes represented among the overpredicted substances were ketones (5), esters (5), carboxylic acids (4), alcohols (3), and heterocyclic compounds (3). Among the 24 substances labeled as surfactants, the BCOP test method overpredicted 25% (6/24).

The BCOP test method overpredicted 35 liquids and 7 solids. Considering the proportion of the total available database, the BCOP test method appears more likely to overpredict liquids (88/118 or 75%) than solids (30/118 or 25%).

According to the EU classification system (see **Annex III**), alcohols (2) were most often underpredicted (i.e., false negatives) by the BCOP test method. As can be seen in **Table 6-16**, none of the 24 substances labeled as surfactants was underpredicted by the BCOP test method (0% [0/24]).

The BCOP test method underpredicted five solids and one liquid. As a proportion of the total available database, solids (30/118 or 25%) appear more likely than liquids (88/118 or 75%) to be underpredicted by the BCOP test method.

Table 6-17 shows how the BCOP test method performance statistics were affected by excluding from the data set problematic classes (i.e., those that gave the most discordant results, according to the EU classification system) identified in the BCOP BRD (ICCVAM 2006a). In general, the exclusion of alcohols, ketones, or solids individually resulted in small changes in the performance statistics. Exclusion of both alcohols and ketones improved the overall classification rate: 53% (50/94) versus 50% (59/118) for all compounds in the database. The classification of ocular corrosives/severe irritants was most improved by the exclusion of problematic classes. Using the entire database, 79% (26/33) of severe ocular corrosives/severe irritants were accurately classified, while removal of solids resulted in 91% (21/23) correct classification. Removal of alcohols, ketones, and solids resulted in correct classification of 95% (20/21) ocular corrosives/severe irritants. Evaluation of overpredicted substances shows 64% (7/11) of hydrocarbons were overpredicted (**Table 6-16**). Compared to the entire database, exclusion of hydrocarbons improved overall correct classification (52% [56/107)] versus 50% [62/121]) and slightly improved identification of substances Not Labeled as Irritants (36% [19/53] versus 34% [22/64]) (**Table 6-17**).

Abbreviations: BCOP= bovine corneal opacity and permeability; EU = European Union; N = number of substances used in this analysis/total number of substances in the study.

[1] EU classification system (EU 2001).

[2] Not Labeled (NL) = Not Labeled as Irritant.

[3] Chemical classes included in this table are represented by at least five substances tested in the BCOP test method, and assignments are based upon National Library of Medicine medical subject heading (MeSH) categories (www.nlm.nih.gov/mesh) as defined in Annex I.

Table 6-18 shows how the ability of the BCOP test method to distinguish substances not labeled as irritants was affected by exclusion of problematic classes from the data set. Exclusion of problematic classes individually or in combination had a minimal effect on accuracy (64% versus 60% to 66%) and specificity (24% to 35%). Sensitivity was 100% using the overall database and therefore remained unchanged. None of the R41 substances was classified by the BCOP test method as not labeled as an irritant. Exclusion of hydrocarbons resulted in modest improvement in overall performance in identifying substances not labeled as irritants (see **Table 6-18**). Accuracy increased from 64% (76/118) to 68% (73/107). The false positive rate decreased from 66% (42/64) to 64% (34/53), while the false negative rate remained 0% (0/54 versus 0/54).

6.5 FHSA Classification System: BCOP Test Method Accuracy

The six reports used in the accuracy evaluation (Gautheron et al. 1994, Balls et al. 1995, Swanson et al. 1995, Southee 1998, Swanson and Harbell 2000, and Bailey et al. 2004) included BCOP data on 194 and 179 substances that had sufficient *in vivo* data to be assigned an ocular irritancy classification according to the FHSA-20% and FHSA-67% classification systems, respectively (FHSA 2005) (see **Annex III**). Among these studies, Gautheron et al. (1994), Balls et al. (1995), and Southee (1998) provided BCOP data for substances tested in multiple laboratories and thus required that a consensus *in vitro* classification be assigned to each substance. Based on results from *in vivo* rabbit eye experiments, 76% (147/194) and 74% (132/179) were classified as irritants in FHSA-20% and FHSA-67%, respectively, while 24% (47/194) and 26% (47/179) were classified as Not Labeled in FHSA-20% and FHSA-67%, respectively.

6.5.1 Ability to Distinguish Not Labeled Substances from All Other Classes

ICCVAM also evaluated the ability of the BCOP test method to distinguish Not Labeled substances from irritants using the FHSA-20% and FHSA-67% classification systems.

Ability to Distinguish Not Labeled Substances from All Other Classes using the FHSA-20% Classification System

ICCVAM evaluated the ability of the BCOP test method to distinguish Not Labeled substances from irritants using the FHSA-20% classification system. Using this approach for the 194 substances, the BCOP test method has an overall accuracy of 83% (161/194), a sensitivity of 95% (139/147), a specificity of 47% (22/47), a false positive rate of 53% (25/47), and a false negative rate of 5% (8/147) (**Table 6-19**).

As detailed below, the results from each individual study were also evaluated separately.

Gautheron et al. (1994): Based upon the *in vivo* rabbit data, 52 substances could be assigned an FHSA-20% classification. Based on these 52 substances, the BCOP test method has an accuracy of 83% (43/52), sensitivity of 88% (35/40), specificity of 67% (8/12), false positive rate of 33% (4/12), and a false negative rate of 13% (5/40) (**Table 6-19**).

Balls et al. (1995): Based upon the *in vivo* rabbit data, 58 substances could be assigned an FHSA-20% classification. Based on these 58 substances, the BCOP test method has an accuracy of 91% (53/58), sensitivity of 93% (50/54), specificity of 75% (3/4), false positive rate of 25% (1/4), and a false negative rate of 7% (4/54) (**Table 6-19**).

Swanson et al. (1995): Based upon the *in vivo* rabbit data, 9 substances could be assigned an FHSA-20% classification. Based on these 9 substances, the BCOP test method has an accuracy of 89% (8/9), sensitivity of 100% (8/8), specificity of 0% (0/1), false positive rate of 100% (1/1), and a false negative rate of 0% (0/8) (**Table 6-19**).

Southee (1998): Based upon the *in vivo* rabbit data, 15 substances could be assigned an FHSA-20% classification. Based on these 15 substances, the BCOP test method has an accuracy of 93% (14/15), sensitivity of 93% (13/14), specificity of 100% (1/1), false positive rate of 0% (0/1), and a false negative rate of 7% (1/14) (**Table 6-19**).

Swanson and Harbell (2000): Based upon the *in vivo* rabbit data, 8 substances could be assigned an FHSA-20% classification. Based on these 8 substances, the BCOP test method has an accuracy of 75% (6/8), sensitivity of 100% (6/6), specificity of 0% (0/2), false positive rate of 100% (2/2), and a false negative rate of 0% (0/6) (**Table 6-19**).

Bailey et al. (2004): Based upon the *in vivo* rabbit data, 15 substances could be assigned an FHSA-20% classification. Based on these 15 substances, the BCOP test method has an accuracy of 73% (11/15),

sensitivity of 88% (7/8), specificity of 57% (4/7), false positive rate of 43% (3/7), and a false negative rate of 13% (1/8) (**Table 6-19**).

AMCP BRD (2008): Based upon the *in vivo* rabbit data, 63 substances could be assigned an FHSA-20% classification. Based on these 63 substances, the BCOP test method has an accuracy of 67% (42/63), sensitivity of 100% (42/42), specificity of 0% (0/21), false positive rate of 100% (21/21), and a false negative rate of 0% (0/42) (**Table 6-19**).

[1] FHSA-20% classification system (2005): Not Labeled vs. Irritant.

Ability to Distinguish Not Labeled Substances from All Other Classes using the FHSA-67% Classification System

ICCVAM evaluated the ability of the BCOP test method to distinguish Not Labeled substances from irritants using the FHSA-67% classification system. Using this approach for the 179 substances, the BCOP test method has an overall accuracy of 83% (148/179), a sensitivity of 95% (126/132), a specificity of 47% (22/47), a false positive rate of 53% (25/47), and a false negative rate of 5% (6/132) (**Table 6-20**).

As detailed below, the results from each individual study were also evaluated separately.

Gautheron et al. (1994): Based upon the *in vivo* rabbit data, 48 substances could be assigned an FHSA-67% classification. Based on these 48 substances, the BCOP test method has an accuracy of 83% (40/48), sensitivity of 89% (32/36), specificity of 67% (8/12), false positive rate of 33% (4/12), and a false negative rate of 11% (4/36) (**Table 6-20**).

Balls et al. (1995): Based upon the *in vivo* rabbit data, 52 substances could be assigned an FHSA-67% classification. Based on these 52 substances, the BCOP test method has an accuracy of 94% (49/52), sensitivity of 96% (46/48), specificity of 75% (3/4), false positive rate of 25% (1/4), and a false negative rate of 4% (2/48) (**Table 6-20**).

Swanson et al. (1995): Based upon the *in vivo* rabbit data, eight substances could be assigned an FHSA-67% classification. Based on these 8 substances, the BCOP test method has an accuracy of 88% (7/8), sensitivity of 100% (7/7), specificity of 0% (0/1), false positive rate of 100% (1/1), and a false negative rate of 0% (0/7) (**Table 6-20**).

Southee (1998): Based upon the *in vivo* rabbit data, 14 substances could be assigned an FHSA-67% classification. Based on these 14 substances, the BCOP test method has an accuracy of 100% (14/14), sensitivity of 100% (13/13), specificity of 100% (1/1), false positive rate of 0% (0/1), and a false negative rate of 0% (0/13) (**Table 6-20**).

Swanson and Harbell (2000): Based upon the *in vivo* rabbit data, seven substances could be assigned an FHSA-67% classification. Based on these 7 substances, the BCOP test method has an accuracy of 71% (5/7), sensitivity of 100% (5/5), specificity of 0% (0/2), false positive rate of 100% (2/2), and a false negative rate of 0% (0/5) (**Table 6-20**).

Bailey et al. (2004): Based upon the *in vivo* rabbit data, 14 substances could be assigned an FHSA-67% classification. Based on these 14 substances, the BCOP test method has an accuracy of 71% (10/14), sensitivity of 86% (6/7), specificity of 57% (4/7), false positive rate of 43% (3/7), and a false negative rate of 14% (1/7) (**Table 6-20**).

AMCP BRD (2008): Based upon the *in vivo* rabbit data, 63 substances could be assigned an FHSA-67% classification. Based on these 63 substances, the BCOP test method has an accuracy of 67% (42/63), sensitivity of 100% (42/42), specificity of 0% (0/21), false positive rate of 100% (21/21), and a false negative rate of 0% (0/42) (Table 6-20).

6.5.2 Discordant Results According to the FHSA Classification System

In order to evaluate discordant responses of the BCOP test method relative to the *in vivo* hazard classification, several accuracy subanalyses were performed. These included specific classes of chemicals with sufficiently robust numbers of substances (n ≥5), as well as certain properties of interest considered relevant to ocular toxicity testing (e.g., surfactants and physical form, respectively).

Discordant Results According to the FHSA-20% Classification System

Table 6-21 shows how the ability of the BCOP test method to distinguish substances not labeled as irritants was affected by exclusion of problematic classes from the data set. Exclusion of problematic classes individually or in combination had a minimal or no effect on accuracy (83% versus 80% to 84%), specificity (94% to 98%) and specificity (36% to 47%). Exclusion of hydrocarbons also resulted no significant improvement in overall performance in identifying substances not labeled as irritants. However, a slightly higher false positive rate and slightly lower false negative rate occurred with exclusion of discordant classes (see **Table 6-21**).

Discordant Results According to the FHSA-67% Classification System

Table 6-22 shows how the ability of the BCOP test method to distinguish substances not labeled as irritants was affected by exclusion of problematic classes from the data set. Exclusion of problematic classes individually or in combination had a minimal or no effect on accuracy (83% versus 80% to 83%), specificity (95% to 99%) and specificity (36% to 47%). Exclusion of hydrocarbons also resulted no significant improvement in overall performance in identifying substances not labeled as irritants. However, a slightly higher false positive rate and slightly lower false negative rate occurred with exclusion of discordant classes (see **Table 6-22**).

7.0 Bovine Corneal Opacity and Permeability Test Method Reliability

Assessment of test method reliability (intralaboratory repeatability and intra- and interlaboratory reproducibility) is essential to any evaluation of the performance of an alternative test method (ICCVAM 2003). Quantitative and qualitative evaluations of BCOP test method reliability have been conducted previously (ICCVAM 2006a).

However, additional qualitative analyses of test method reproducibility evaluated the extent of agreement of BCOP hazard classifications among the laboratories. Given that the performance of the BCOP test method was similar for the EPA and FHSA classification systems, additional reliability analyses were not conducted for the FHSA classification system.

7.1 Interlaboratory Reproducibility of Hazard Classification Category Using the GHS Classification System

Reliability analyses for the BCOP test method were evaluated for the following three studies: Balls et al. (1995), Gautheron et al. (1994), and Southee (1998).

Balls et al. (1995): Of 14 substances classified by the GHS as Not Labeled, 29% (4/14) were correctly identified, while two of four GHS Category 2B substances (50%) were correctly identified, 29% (4/14) substances classified as GHS Category 2A were correctly identified, and 77% (17/22) GHS Category 1 substances were correctly identified.

The five participating laboratories were in 100% agreement on the ocular irritancy classification when distinguishing Not Labeled substances from all other classes of 92% (55/60) substances (**Table 7-1**).

All five participating laboratories agreed on the classification of 88% (15/17) substances that were correctly identified as GHS Category 1, 0% (0/4) substances correctly classified as GHS Category 2A, 50% (1/2) substances correctly classified as GHS Category 2B, and 50% (2/4) substances correctly classified as GHS Not Classified (**Table 7-2**).

The extent of agreement between testing laboratories was greatest for substances identified from *in vivo* rabbit eye data as corrosives or severe irritants when compared to any other combination of *in vivo* and *in vitro* results. Eighty-eight percent (15/17) of the accurately identified severe substances were shown to have 100% classification agreement among testing laboratories (**Table 7-2**).

There was 100% agreement on the 10 false positive substances among the five laboratories.

Gautheron et al. (1994): Of 34 substances classified by the GHS as Not Classified, 38% (13/34) were correctly identified, while 0% (0/2) GHS Category 2B substances were correctly identified, 33% (1/3) substances classified as GHS Category 2A was correctly identified, and 75% (6/8) GHS Category 1 substances were correctly identified.

The 11–12 participating laboratories were in 100% agreement on the ocular irritancy classification when distinguishing substances not labeled as irritants from all other classes of 65% (34/52) substances (**Table 7-1**).

All 11–12 participating laboratories agreed on the classification of 67% (4/6) substances that were correctly identified as GHS Category 1, 0% (0/1) substances correctly classified as GHS Category 2A, and 0% (0/13) substance correctly classified as GHS Not Classified (**Table 7-2**).

The extent of agreement between testing laboratories was greatest for substances identified from *in vivo* rabbit eye data as corrosives or severe irritants when compared to any other combination of *in vivo* and *in vitro* results: 67% (4/6) of the accurately identified severe substances were shown to have 100% classification agreement among testing laboratories) (**Table 7-2**).

Of the 21 false positive substances, 90% (19/21) were shown to have 100% agreement among the 11-12 laboratories.

Southee (1998): Of 3 substances classified by the GHS as Not Classified, 67% (2/3) were correctly identified, while 50% (1/2) GHS Category 2B substances was correctly identified, 67% (2/3) of substances classified as GHS Category 2A were correctly identified, and 57% (4/7) of GHS Category 1 substances were correctly identified.

The three participating laboratories were in 100% agreement on the ocular irritancy classification when distinguishing substances not labeled as irritants from all other classes of 88% (14/16) substances (**Table 7-1**).

All three participating laboratories agreed on the classification of 100% (4/4) substances that were correctly identified as GHS Category 1, 50% (1/2) substances correctly classified as GHS Category 2A, 100% (1/1) substance correctly classified as GHS Category 2B, and 100% (2/2) substances correctly classified as GHS Not Classified (**Table 7-2**).

Regarding the 1 false positive substance, there was 100% agreement among the three laboratories.

[1] GHS classification system (UN 2007).

7.2 Interlaboratory Reproducibility of Hazard Classification Category Using the EPA Classification System

Balls et al. (1995): Both of the substances classified by the EPA as Category IV (100%) were correctly identified, while 29% (6/21) EPA Category III substances were correctly identified; 29% (4/14) EPA Category II substances were correctly identified, and 74% (14/19) EPA Category I substances were correctly identified.

The five participating laboratories were in 100% agreement on the ocular irritancy classification when assessing substances not labeled as irritants from all other classes of 93% (56/60) substances (**Table 7-3**).

All five participating laboratories agreed on the classification of 79% (11/14) substances that were correctly identified as EPA Category I, 0% (0/4) substances correctly classified as EPA Category II, 67% (4/6) substances correctly classified as EPA Category III, and 50% (1/2) substances correctly classified as EPA Category IV (**Table 7-4**).

When compared to any other combination of *in vivo* and *in vitro* results, the extent of agreement between testing laboratories was greatest for substances identified from *in vivo* rabbit eye data as corrosives or severe irritants. Of the accurately identified severe substances, 93% (13/14) were shown to have 80%–100% classification agreement among testing laboratories (**Table 7-4**).

Gautheron et al. (1994): Of 13 substances classified by the EPA as Category IV, 69% (9/13) were correctly identified, while 43% (9/21) EPA Category III substances were correctly identified, 25% (1/4 substances classified as EPA Category II was correctly identified, and 86% (6/7) EPA Category I substances were correctly identified.

The 11–12 participating laboratories were in 100% agreement on the ocular irritancy classification when assessing substances not labeled as irritants from all other classes of 65% (34/52) substances (**Table 7-3**).

All 11–12 participating laboratories agreed on the classification of 67% (4/6) substances that were correctly identified as EPA Category I, 0% (0/1) substances correctly classified as EPA Category II, 22% (2/9) substances correctly classified as EPA Category III, and 0% (0/9) substances correctly classified as EPA Category IV (**Table 7-4**).

All 4 false positive substances (100%) were shown to have 100% agreement among the 11–12 laboratories (**Table 7-4**).

Southee (1998): The one substance classified by the EPA as Category IV was correctly identified (100%), while 33% (2/6) EPA Category III substances were correctly identified, 50% (1/2) EPA Category II substances were correctly identified, and 50% (3/6) EPA Category I substances were correctly identified.

The three participating laboratories were in 100% agreement on the ocular irritancy classification when assessing substances not labeled as irritant from all other classes of 88% (14/16) substances (**Table 7-3**).

All three participating laboratories agreed on the classification of 100% (3/3) substances correctly identified as EPA Category I, 100% (1/1) substance correctly classified as EPA Category II, 100% (2/2) substances correctly classified as EPA Category III, and 100% (1/1) substance correctly classified as EPA Category IV (**Table 7-4**).

Abbreviations: BCOP = bovine corneal opacity and permeability; EPA = U.S. Environmental Protection Agency; IV = Not Labeled as Irritant; III = mild irritant; II = moderate irritant; I = severe irritant.

[1] EPA classification system (EPA 2003a).

[2] Due to the lack of appropriate *in vivo* data (e.g., studies were terminated too early to assess reversibility of effects), a EPA classification could not be made for two substances. See **Section 6.1** for a description of the rules followed to classify the ocular irritancy of test substances tested multiple times *in vitro*.

7.3 Interlaboratory Reproducibility of Hazard Classification Category Using the EU Classification System

Balls et al. (1995): Of 16 substances classified by the EU as Not Labeled, 25% (4/16) were correctly identified, while 47% (7/15) EU R36 substances were correctly identified, and 74% (14/19) EU R41 substances were correctly identified.

The five participating laboratories were in 100% agreement on the ocular irritancy classification when assessing substances not labeled as irritant from all other classes of 93% (56/60) substances (**Table 7-5**).

All five participating laboratories agreed on the classification of 86% (12/14) substances that were correctly identified as EU R41, 29% (2/7) substances correctly classified as EU R36, and 50% (2/4) substances correctly classified as EU Not Labeled (**Table 7-6**).

When compared to any other combination of *in vivo* and *in vitro* results, the extent of agreement between testing laboratories was greatest for substances identified from *in vivo* rabbit eye data as corrosives or severe irritants. All (100%) of the accurately identified severe substances were shown to have 95%–100% classification agreement among testing laboratories (**Table 7-6**).

Of the 12 false positive substances, 100% (12/12) were shown to have 100% agreement among the 5 laboratories (**Table 7-6**).

Gautheron et al. (1994): Of 36 substances classified by the EU as Not Labeled, 36% (13/36) were correctly identified, while 50% (2/4) EU R36 substances were correctly identified, and 75% (6/8) EU R41 substances were correctly identified.

The 11–12 participating laboratories were in 100% agreement on the ocular irritancy classification when assessing non labeled substances from all other classes of 65% (34/52) substances (**Table 7-5**).

All 11–12 participating laboratories agreed on the classification of 67% (4/6) substances that were correctly identified as EU R41, 0% (0/2) substances correctly classified as EU R36, and 54% (7/13) substances correctly classified as EU Not Labeled (**Table 7-6**).

Of the 23 false positive substances, 91% (21/23) were shown to have 100% agreement among the 11-12 laboratories (**Table 7-6**).

Southee (1998): Of the 4 substances classified by the EU as Not Labeled, 50% (2/4) were correctly identified, while 50% (2/4) EU R36 substances were correctly identified, and 67% (4/6) EU R41 substances were correctly identified.

The three participating laboratories were in 100% agreement on the ocular irritancy classification when assessing substances not labeled as irritant from all other classes of 88% (14/16) substances (**Table 7-5**).

All three participating laboratories agreed on the classification of 100% (4/4) substances correctly identified as EU R41, 100% (3/3) substances correctly classified as EU R36, and 100% (2/2) substances correctly classified as EU Not Labeled (**Table 7-6**).

Of the 2 false positive substances, 50% (1/2) was shown to have 100% agreement among the three laboratories (**Table 7-6**).

Abbreviations: BCOP = bovine corneal opacity and permeability; EU = European Union; N = number of substances.

A "+" indicates that the substance was assigned an overall classification of corrosive or a severe irritant (Category R41). A "-" indicates that the substance was assigned an overall classification of nonsevere irritant (Category R36) or Not Labeled. A "?" indicates that, due to the lack of appropriate *in vivo* data (e.g., studies were terminated too early to assess reversibility of effects; insufficient dose volume), an EU classification could not be made. See Section 6.1 for a description of the rules followed to classify the ocular irritancy of test substances tested multiple times *in vitro*.

8.0 Bovine Corneal Opacity and Permeability Test Method Data Quality

8.1 Adherence to National and International GLP Guidelines

The original evaluation of BCOP test method data quality is detailed in the previous BCOP BRD (ICCVAM 2006a). As indicated in Section 8.0 of the AMCP BRD (2008) submission, it could not be determined whether all of the *in vitro* data contained in the AMCP BRD were generated under full GLP compliance. Where possible, that information is contained in the spreadsheets that form the database from which the AMCP BRD was generated. All of the new *in vitro* data that were generated during the course of constructing the current ICCVAM 2010 BRD were conducted with full GLP compliance.

9.0 Reports in the Peer-Reviewed Literature

NICEATM located among the peer-reviewed literature a total of four BCOP studies published since the previous evaluation of the BCOP method for identification of ocular corrosives and severe irritants (ICCVAM 2006a) that contained BCOP data (Cater and Harbell 2006, 2008; Debbasch et al. 2005; Van Goethem et al. 2006). The four publications contained BCOP test method analyses; however, none of these publications included raw data and therefore were not added to the database.

In Debbasch et al. (2005), 12 makeup removers were tested both in the BCOP and in a clinical in-use test under ophthalmological control after their application to the external eyelid. The undiluted test product (750 μL) was pipetted onto the corneas and exposure conducted for 4 hours. Corneal opacity was determined using an adapted spectrophotometer and barrier disruption by fluorescein update using OD_{490} mm. *In vitro* scores were classified according to Gautheron et al. (1994) and Harbell and Curren (1998). However, no *in vivo* rabbit eye data were reported, and these data have not been obtained. For this reason, Debbasch et al. (2005) was not included in the BCOP performance analyses detailed in this BRD.

In Cater and Harbell (2006), surfactant-based "rinse-off" personal care formulations were tested in the BCOP test method using slight modifications of the BCOP protocol reported by Sina et al. (1995). Corneas were exposed to the test substances (750 μL) for 10, 30, or 60 minutes either undiluted or diluted in deionized water. Corneas were evaluated for opacity, fluorescein uptake, and histological alterations. No *in vivo* rabbit reference data were reported, and thus this study was not included in the BCOP performance analyses detailed in this BRD.

Van Goethem et al. (2006) tested 20 substances in the BCOP test method (7 compounds classified as GHS Not Classified and 13 GHS Category 1). These results were published in Vanparys et al. (1993) and Gautheron et al. (1994), which were included in the previous BCOP BRD (ICCVAM 2006a).

In Cater and Harbell (2008), the BCOP test method was used on four commercial and one unregistered body wash developed for children or as mild bath products. The purpose was to determine if the BCOP test method could be used as a prediction model for relative ranking of human eye responses under conditions of a standard human eye sting test to surfactant-based formulations. Test articles were prepared as 25% solutions in deionized water; 750 μL was applied to the corneas for a 30 minute exposure. Following exposure, opacity and fluorescein uptake were determined *in vitro*, but no *in vivo* rabbit eye data were reported.

10.0 Animal Welfare Considerations (Reduction, Refinement, and Replacement)

10.1 How the BCOP Test Method Will Reduce, Refine, or Replace Animal Use

ICCVAM promotes the scientific validation and regulatory acceptance of new methods that reduce, refine, or replace animal use where scientifically feasible. Refinement, reduction, and replacement are known as the "three Rs" of animal protection. These principles of humane treatment of laboratory animals are described as:

Reducing animal use through improved science and experimental design

Refining experimental procedures such that animal suffering is minimized

Replacing animal models with nonanimal procedures (e.g., *in vitro* technologies) where possible (Russell and Burch 1992)

The BCOP test method refines animal use. Because these animals are being humanely killed for nonlaboratory purposes, the testing procedure inflicts no additional pain or distress on animals. Substances that are identified as corrosive or severe irritants *in vitro* are excluded from *in vivo* testing. Furthermore, the ability to identify mild and moderate ocular irritants would eliminate the need for *in vivo* testing, thus sparing rabbits from the pain associated with these types of substances.

The BCOP test method can also reduce animal use because the test method utilizes animal species routinely raised as a food source in large numbers and thereby replaces laboratory animals. Additionally, with the ability to identify ocular corrosives and severe ocular irritants as well as mild and moderate ocular irritants from the *in vitro* method, the animals that would have been used in the *in vivo* rabbit eye test would be spared.

10.2 Requirement for the Use of Animals

Although cattle are required as a source of corneas for this *in vitro* test method, only cattle humanely killed for food or other nonlaboratory purposes are used as eye donors (i.e., no live animals are used in this test method).

11.0 Practical Considerations

Practical considerations for the BCOP method are detailed in the previous BCOP BRD (ICCVAM 2006a).

13.0 Glossary[2]

Accuracy:[3] (a) The closeness of agreement between a test method result and an accepted reference value. (b) The proportion of correct outcomes of a test method. It is a measure of test method performance and one aspect of "relevance." The term is often used interchangeably with *concordance* (see also *two-by-two table*). Accuracy is highly dependent on the prevalence of positives in the population being examined.

Assay:[3] The experimental system used. Often used interchangeably with *test* and *test method*.

Benchmark control: A sample containing all components of a test system and treated with a known substance (i.e., the benchmark substance) to induce a known response. The sample is processed with test substance-treated and other control samples to compare the response produced by the test substance to the benchmark substance to allow for an assessment of the sensitivity of the test method to assess a specific chemical class or product class.

Benchmark substance: A substance used as a standard for comparison to a test substance. A benchmark substance should have the following properties:

- a consistent and reliable source(s)
- structural and functional similarity to the class of substances being tested
- known physical/chemical characteristics
- supporting data on known effects
- known potency in the range of the desired response

Blepharitis: Inflammation of the eyelids.

Bulbar conjunctiva: The portion of the conjunctiva that covers the outer surface of the eye.

Chemosis: A form of eye irritation in which the membranes that line the eyelids and surface of the eye (*conjunctiva*) become swollen.

Classification system: An arrangement of quantified results or data into groups or categories according to previously established criteria.

Coded substances: Substances labeled by code rather than name so that they can be tested and evaluated without knowledge of their identity or anticipation of test results. Coded substances are used to avoid intentional or unintentional bias when evaluating laboratory or test method performance.

Coefficient of variation: A statistical representation of the precision of a test. It is expressed as a percentage and is calculated as follows:

$$\left(\frac{standard\ deviation}{mean}\right) \times 100\%$$

Concordance:[3] The proportion of all substances tested that are correctly classified as positive or negative. It is a measure of test method performance and one aspect of *relevance*. The term is often used interchangeably with *accuracy* (see also *two-by-two table*). Concordance is highly dependent on the prevalence of positives in the population being examined.

[2] The definitions in this Glossary are restricted to their uses with respect to the Draize rabbit eye test method and the BCOP test method.

[3] Definition used by the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM 2003).

Conjunctiva: The mucous membrane that lines the inner surfaces of the eyelids and folds back to cover the front surface of the eyeball, except for the central clear portion of the outer eye (the cornea). The conjunctiva is composed of three sections: palpebral conjunctiva, bulbar conjunctiva, and fornix.

Conjunctival sac: The space located between the eyelid and the conjunctiva-covered eyeball. Substances are instilled into the sac to conduct an *in vivo* eye test.

Cornea: The transparent part of the coat of the eyeball that covers the iris and pupil and admits light to the interior.

Corneal opacity: Measurement of the extent of opaqueness of the cornea following exposure to a test substance. Increased corneal opacity is indicative of damage to the cornea. Opacity can be evaluated subjectively as done in the Draize rabbit eye test, or objectively with an instrument such as an opacitometer.

Corneal permeability: Quantitative measurement of damage to the corneal epithelium by a determination of the amount of sodium fluorescein dye that passes through all corneal cell layers.

Corrosion: Destruction of tissue at the site of contact with a substance.

Corrosive: A substance that causes irreversible tissue damage at the site of contact.

Endpoint:[3] The biological process, response, or effect assessed by a test method.

False negative:[3] A substance incorrectly identified as negative by a test method.

False negative rate:[3] The proportion of all positive substances falsely identified by a test method as negative (see *two-by-two table*). It is one indicator of test method accuracy.

False positive:[3] A substance incorrectly identified as positive by a test method.

False positive rate:[3] The proportion of all negative substances that are falsely identified by a test method as positive (see *two-by-two table*). It is one indicator of test method accuracy.

Fibrous tunic: The outer of the three membranes of the eye, comprising the cornea and the sclera; also called *tunica fibrosa oculi*.

Globally Harmonized System (GHS): A classification system presented by the United Nations that provides (a) a harmonized criteria for classifying substances and mixtures according to their health, environmental and physical hazards, and (b) harmonized hazard communication elements, including requirements for labeling and safety data sheets.

Good Laboratory Practices (GLP):[3] Regulations promulgated by the U.S. Food and Drug Administration and the U.S. Environmental Protection Agency, and principles and procedures adopted by the Organization for Economic Cooperation and Development and Japanese authorities that describe record keeping and quality assurance procedures for laboratory records that will be the basis for data submissions to national regulatory agencies.

Hazard:[3] The potential for an adverse health or ecological effect. A hazard potential results only if an exposure occurs that leads to the possibility of an adverse effect being manifested.

Interlaboratory reproducibility:[3] A measure of whether different qualified laboratories using the same protocol and test substances can produce qualitatively and quantitatively similar results. Interlaboratory reproducibility is determined during the prevalidation and validation processes and indicates the extent to which a test method can be transferred successfully among laboratories.

Intralaboratory repeatability:[3] The closeness of agreement between test results obtained within a single laboratory when the procedure is performed on the same substance under identical conditions within a given time period.

Intralaboratory reproducibility:[3] The first stage of validation; a determination of whether qualified people within the same laboratory can successfully replicate results using a specific test protocol at different times.

In vitro: In glass. Refers to assays that are carried out in an artificial system (e.g., in a test tube or petri dish) and typically use single-cell organisms, cultured cells, cell-free extracts, or purified cellular components.

***In vitro* irritancy score:** An empirically derived formula used in the BCOP assay whereby the mean opacity and mean permeability values for each treatment group are combined into a single *in vitro* score for each treatment group. The *in vitro* irritancy score = mean opacity value + (15 x mean permeability value).

In vivo : In the living organism. Refers to assays performed in multicellular organisms.

Iris: The contractile diaphragm perforated by the pupil and forming the colored portion of the eye.

Negative control: An untreated sample containing all components of a test system, except the test substance solvent, which is replaced with a known nonreactive material, such as water. This sample is processed with test substance-treated samples and other control samples to determine whether the solvent interacts with the test system.

Negative predictivity:[3] The proportion of correct negative responses among substances testing negative by a test method (see *two-by-two table*). It is one indicator of test method accuracy. Negative predictivity is a function of the sensitivity of the test method and the prevalence of negatives among the substances tested.

Neuroectodermal tunic: The innermost of three membranes of the eye, comprising the retina.

Nictating (nictitating) membrane: The membrane that moves horizontally across the eye in some animal species (e.g., rabbit, cat) to provide additional protection in particular circumstances. It may be referred to as the *third eyelid*.

Nonsevere irritant: (a) A substance that causes tissue damage in the eye following application to the anterior surface of the eye; the tissue damage is reversible within 21 days of application and the observed adverse effects in the eye are less severe than observed for a severe irritant. (b) Substances that are classified as GHS Category 2A or 2B; EPA Category II, III, or IV; or EU R36 ocular irritants.

Not Labeled: (a) A substance the produces no changes in the eye following application to the anterior surface of the eye. (b) Substances that are not classified as GHS Category 1, 2A, or 2B; or EU R41 or R36 ocular irritants.

Ocular: Of or relating to the eye.

Ocular corrosive: A substance that causes irreversible tissue damage in the eye following application to the anterior surface of the eye.

Ocular irritant: A substance that produces a reversible change in the eye following application to the anterior surface of the eye.

Opacitometer: An instrument used to measure *corneal opacity* by quantitatively evaluating light transmission through the cornea. The instrument has two compartments, each with its own light source and photocell. One compartment is used for the treated cornea, while the other is used to calibrate and zero the instrument. The difference between photocell signals in the two compartments is measured electronically as a change in voltage and is displayed digitally, generating numerical opacity values with arbitrary units.

Palpebral conjunctiva: The part of the conjunctiva that covers the inner surface of the eyelids.

Pannus: A specific type of corneal inflammation that begins within the conjunctiva and with time spreads to the cornea. Also referred to as *chronic superficial keratitis*.

Performance:[3] The accuracy and reliability characteristics of a test method (see *accuracy*, *reliability*).

pH: A measure of the acidity or alkalinity of a solution. pH 7.0 is neutral; higher pHs are alkaline, lower pHs are acidic.

Positive control: A sample containing all components of a test system and treated with a substance known to induce a positive response, which is processed with the test substance-treated and other control samples to demonstrate the sensitivity of each experiment and to allow for an assessment of variability in the conduct of the assay over time.

Positive predictivity:[3] The proportion of correct positive responses among substances testing positive by a test method (see *two-by-two table*). It is one indicator of test method accuracy. Positive predictivity is a function of the sensitivity of the test method and the prevalence of positives among the substances tested.

Prevalence:[3] The proportion of positives in the population of substances tested (see *two-by-two table*).

Protocol:[3] The precise, step-by-step description of a test method, including a listing of all necessary reagents, criteria, and procedures for evaluation of the test data.

Quality assurance:[3] A management process by which adherence to laboratory testing standards, requirements, and record keeping procedures is assessed independently by individuals other than those performing the testing.

Reduction alternative:[3] A new or modified test method that reduces the number of animals required.

Reference test method:[3] The accepted *in vivo* test method used for regulatory purposes to evaluate the potential of a test substance to be hazardous to the species of interest.

Refinement alternative:[3] A new or modified test method that refines procedures to lessen or eliminate pain or distress in animals, or enhances animal well-being.

Relevance:[3] The extent to which a test method correctly predicts or measures the biological effect of interest in humans or another species of interest. Relevance incorporates consideration of the *accuracy* or *concordance* of a test method.

Reliability:[3] A measure of the degree to which a test method can be performed reproducibly within and among laboratories over time. It is assessed by calculating intra- and interlaboratory reproducibility and intralaboratory repeatability.

Replacement alternative:[3] A new or modified test method that replaces animals with nonanimal systems or one animal species with a phylogenetically lower one (e.g., a mammal with an invertebrate).

Reproducibility:[3] The consistency of individual test results obtained in a single laboratory (intralaboratory reproducibility) or in different laboratories (interlaboratory reproducibility) using the same protocol and test substances (see intra- and inter-laboratory reproducibility).

Sclera: The tough, fibrous tissue that extends from the cornea to the optic nerve at the back of the eye.

Sensitivity:[3] The proportion of all positive substances that are classified correctly as positive in a test method. It is a measure of test method accuracy (see *two-by-two table*).

Secondary bacterial keratitis: Inflammation of the cornea that occurs secondary to another insult that compromised the integrity of the eye.

Severe irritant: (a) A substance that causes tissue damage in the eye following application to the anterior surface of the eye that is not reversible within 21 days of application or causes serious physical

decay of vision. (b) Substances that are classified as EPA Category I, GHS Category 1, or EU R41 ocular irritants.

Solvent control: An untreated sample containing all components of a test system, including the solvent that is processed with the test substance-treated and other control samples to establish the baseline response for the samples treated with the test substance dissolved in the same solvent. When tested with a concurrent negative control, this sample also demonstrates whether the solvent interacts with the test system.

Specificity:[3] The proportion of all negative substances that are classified correctly as negative in a test method. It is a measure of test method accuracy (see *two-by-two table*).

Test:[2] The experimental system used; used interchangeably with *test method* and *assay*.

Test method:[3] A process or procedure used to obtain information on the characteristics of a substance or agent. Toxicological test methods generate information regarding the ability of a substance or agent to produce a specified biological effect under specified conditions. Used interchangeably with *test* and *assay*. See also *validated test method* and *reference test*.

Test method component: Structural, functional, and procedural elements of a test method that are used to develop the test method protocol. These components include unique characteristics of the test method, critical procedural details, and quality control measures.

Tiered testing: A testing strategy where all existing information on a test substance is reviewed, in a specified order, prior to *in vivo* testing. If the irritancy potential of a test substance can be assigned, based on the existing information, no additional testing is required. If the irritancy potential of a test substance cannot be assigned, based on the existing information, a step-wise animal testing procedure is performed until an unequivocal classification can be made.

Toxic keratoconjunctivitis: Inflammation of the cornea and conjunctiva due to contact with an exogenous agent. Used interchangeably with *contact keratoconjunctivitis*, *irritative keratoconjunctivitis* and *chemical keratoconjunctivitis*.

Transferability:[3] The ability of a test method or procedure to be accurately and reliably performed in different, competent laboratories.

Two-by-two table:[3] The two-by-two table can be used for calculating accuracy (concordance) ([a+d]/[a+b+c+d]), negative predictivity (d/[c+d]), positive predictivity (a/[a+b]), prevalence ([a+c]/[a+b+c+d]), sensitivity (a/[a+c]), specificity (d/[b+d]), false positive rate (b/[b+d]), and false negative rate (c/[a+c]).

		New Test Outcome		
		Positive	Negative	Total
Reference Test Outcome	Positive	a	c	a + c
	Negative	b	d	b + d
	Total	a + b	c + d	a + b + c + d

Uvea tract: The middle of three membranes of the eye, comprising the iris, ciliary body, and choroid. Also referred to as the *vascular tunic*.

Validated test method:[3] An accepted test method for which validation studies have been completed to determine the relevance and reliability of this method for a specific proposed use.

Validation:[3] The process by which the reliability and relevance of a procedure are established for a specific purpose.

Vascular tunic: The middle of three membranes of the eye, comprising the iris, ciliary body, and choroid. Also referred to as the *uvea*.

Weight of evidence (process): The strengths and weaknesses of a collection of information are used as the basis for a conclusion that may not be evident from the individual data.

Annex I-1

Chemical and Product Classes of Substances Tested in the BCOP Assay

This page intentionally left blank

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
1-1 (#1)	-	Formulation	Insect repellent
1-2 (#2)	-	Formulation	Insect repellent
1-3 (#3)	-	Formulation	Insect repellent
2-4 (#4)	-	Formulation	Insect repellent
2-7 (#7)	-	Formulation	Insect repellent
2-8 (#8)	-	Formulation	Insect repellent
Acetone	67-64-1	Ketone	Solvent; Antiseptic; Chemical intermediate; Raw material
Alkyl phosphoric acid ester/amine salt	-	Organic salt, Ester, Amine	Petroleum product
All Purpose Cleaner (#5)	-	Formulation	Cleaner
All Purpose Cleaner (#7)	-	Formulation	Cleaner
Allyl alcohol	107-18-6	Alcohol	Pesticide
Aluminum hydroxide	21645-51-2	Alkali, Aluminum compound	Chemical intermediate, Dessicant
2-Aminophenol	95-55-6		Chemical intermediate
Ammonium nitrate	6484-52-2	Inorganic salt, Onium compound	Fertilizer; Chemical intermediate; Industrial explosive
Amway all fabric bleach	-	Formulation	Detergent
Amway automatic dishwashing compound for soft water	-	Formulation	Detergent
Amway automatic dishwashing compound, standard formula	-	Formulation	Detergent

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Amway concrete floor cleaner	-	Formulation	Cleaner
Amway Dish Drops dishwashing liquid	-	Formulation	Detergent
Amway dry chlorine bleach	-	Formulation	Bleach
Amway fabric softener	-	Formulation	Fabric softener
Amway Kool Wash delicate fabric detergent	-	Formulation	Detergent
Amway LOC all purpose cleaner	-	Formulation	Cleaner
Amway prewash liquid	-	Formulation	Detergent
Amway Pursue disinfectant cleaner	-	Formulation	Cleaner
Amway Redu dye stain remover	-	Formulation	Stain remover
Amway SA8 laundry liquid	-	Formulation	Detergent
Amway SA8 limited phos laundry powder	-	Formulation	Detergent
Anthracene	120-12-7	Polycyclic	Dye manufacturing agent
Anti-Dandruff Shampoo (HZY) 100%	-	Formulation	Surfactant-containing formulation
Aromatic hydrocarbon #1	-	Hydrocarbon (cyclic)	Solvent/industrial chemical; Petrochemical product
Aromatic hydrocarbon #2	-	Hydrocarbon (cyclic)	Solvent/industrial chemical; Petrochemical product
Aryl phosponates	-	Not classified	Lubricant additive; Petrochemical product
L-Aspartic acid	70-47-3	Amino acid	Organic intermediate; Fungicides; Germicides

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Baby Shampoo No. 1 (HZP)	-	Formulation	Surfactant-containing formulation
Baby Shampoo No. 2 (HZF)	-	Formulation	Surfactant-containing formulation
Bathroom Cleaner (#6)	-	Formulation	Cleaner
Benchmark-Group 1 (#12)	-	Formulation	Insect repellent
Benchmark-Group 2 (#13)	-	Formulation	Insect repellent
Benzalkonium chloride (100%)	8001-54-5	Onium compound	Surfactant (cationic); Bactericide; Fungicide; Preservative
Benzalkonium chloride (1 %)	8001-54-5	Inorganic salt, Onium compound	Fertilizer; Chemical intermediate; Industrial explosive
Benzalkonium chloride (10%)	8001-54-5	Onium compound	Surfactant (cationic); Bactericide; Fungicide; Preservative
Benzalkonium chloride (5%)	8001-54-5	Onium compound	Surfactant (cationic); Bactericide; Fungicide; Preservative
Benzethonium chloride	121-54-0	Amine, Onium compound	Bactericide
Benzoyl-L-tartaric acid	2743-38-6	Carboxylic acid, Ester	Optical resolution agent
Betaine monohydrate	590-47-6	Amino acid, Onium compound	Not classified
BRIJ-35	9002-92-0	Alcohol	Emulsifier
4-Bromophenetole	589-10-6	Ether	Not classified
Bubble Bath (HZK) 100%	-	Formulation	Surfactant-containing formulation
n-Butanol	71-36-3	Ketone	Solvent; Synthetic flavor; Drycleaning
2-Butoxyethanol	111-76-2	Alcohol	Solvent

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Butyl acetate	123-86-4	Ester	Solvent; Synthetic flavor ingredient
Butyl cellosolve	111-76-2	Alcohol, Ester	Solvent
Butyrolactone	96-48-0	Lactone, Heterocycle	Synthetic intermediate; Solvent
gamma-Butyrolactone	96-48-0	Heterocyclic, Lactone	Synthetic intermediate; Solvent
Captan 90 concentrate	133-06-2	Imide, Organic sulfur compound	Pesticide
4-Carboxybenzaldehyde	619-66-9	Carboxylic acid, Aldehyde	Not classified
Carboxylic acid amides	-	Formulation	Lubricant additive; Petrochemical product
Cetylpyridinium bromide (0.1%)	140-72-7	Heterocyclic, Onium compound	Surfactant (cationic); Germicide; Laboratory reagent
Cetylpyridinium bromide (1%)	140-72-7	Surfactant, cationic	Germicide; Laboratory reagent
Cetylpyridinium bromide (10%)	140-72-7	Heterocyclic, Onium compound	Surfactant (cationic); Germicide; Laboratory reagent
Cetylpyridinium bromide (6%)	140-72-7	Heterocyclic, Onium compound	Surfactant (cationic); Germicide; Laboratory reagent
Chlorhexidine	55-56-1	Amine/Amidine	Disinfectant; Mouthwash; Anti-infective agent
2-Chloro-2,4,4-trimethylpentane	-	Hydrocarbon (halogenated)	Solvent/industrial chemical; Petrochemical product
Clarified slurry oil	-	Hydrocarbon (cyclic)	Petrochemical product
Cleaner/Degreaser (#13)	-	Formulation	Cleaner
Cleansing Gel (HZQ) 100%	-	Formulation	Surfactant-containing formulation
Cutting fluid (conc.) #1	-	Formulation	Cutting fluid; Petrochemical product

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Cutting fluid (conc.) #2	-	Formulation	Cutting fluid; Petrochemical product
Cyclohexanol	108-93-0	Alcohol	Solvent; Chemical intermediate
Cyclohexanone	108-94-1	Ketone, Hydrocarbon (cyclic)	Solvent, Chemical intermediate
Degreaser (#16)	-	Formulation	Degreaser
Deoxycholic acid, sodium salt	302-95-4	Alcohol, Carboxylic acid (salt)	Detergent/Surfactant, Chemical intermediate
Diacetone alcohol	123-42-2	Ketone, Alcohol	Solvent
Dibenzyl phosphate	1623-08-1	Ester, Organophosphorus compound	Not classified
2,6-Dichlorobenzoyl chloride	4659-45-4	Acyl halide	Anti-infective; Anti-fungal; Preservative
2,4-Dichloro-5-sulfamoylbenzoic acid	2736-23-4	Amide, Organic sulfur compound	Intermediate for pharmaceticals, pesticides, perfumes
2,4-Difluoronitrobenzene	446-35-5	Acyl halide	Anti-infective; Anti-fungal; Preservative
1,3-Diisopropylbenzene	99-62-7	Hydrocarbon (cyclic)	Not classified
Dimethylbiguanide	657-24-9	Amidine	Pharmaceutical
2,2-Dimethylbutanoic acid	595-37-9	Carboxylic acid	Pharmaceutical metabolite
2,5-Dimethylhexanediol	110-03-2	Alcohol	Intermediate for pharmaceticals, pesticides, perfumes
Dimethyl sulfoxide	67-68-5	Organic sulfur compound	Solvent
Dodecane	112-40-3	Hydrocarbon (acyclic)	Not classified
EDTA, di-potassium salt	25102-12-9	Amine, Carboxylic acid (salt)	Chelator

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Ethanol	64-17-5	Alcohol	Solvent; Beverages; Antifreeze agent
Ethanol (#14)	64-17-5	Alcohol	Solvent
2-Ethoxyethanol	110-80-5	Alcohol	Solvent
Ethyl acetate	141-78-6	Ester	Solvent; Synthetic flavoring
Ethyl acetoacetate	141-97-9	Carboxylic acid, Ketone	Chemical intermediate, Flavoring agent
2-Ethylhexanol	104-76-7	Alcohol	Intermediate for pharmaceticals, pesticides, perfumes
2-Ethyl-1-hexanol	104-76-7	Alcohol	Solvent; Plasticizer
Ethylhexyl acid phosphate ester	-	Ester, Carboxylic acid	Lubricant additive; Petrochemical product
5-Ethylidene-2-norbornene	16219-75-3	Not classified	Solvent/industrial chemical; Petrochemical product
Ethyl-2-methylacetoacetate	609-14-3	Ketone, Ester	Not classified
3-Ethyltoluene	620-14-4	Hydrocarbon (cyclic)	Not classified
Ethyl trimethyl acetate	3938-95-2	Ester	Solvent
Eye Make-Up Remover (HZH) 100%	-	Formulation	Surfactant-containing formulation
Facial Cleaning Foam (HZR) 25%	-	Formulation	Surfactant-containing formulation
Facial Cleanser (HZZ) 100%	-	Formulation	Surfactant-containing formulation
Floor Cleaner (#10)	-	Formulation	Cleaner
Floor Cleaner (#2)	-	Formulation	Cleaner

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Floor Stripper (#14)	-	Formulation	Floor stripper
Floor Stripper (#17)	-	Formulation	Floor stripper
Floor Stripper (#18)	-	Formulation	Floor stripper
Foam Bath (HZL) 100%	-	Formulation	Surfactant-containing formulation
Fomesafen	72128-02-0	Imide, Ether, Nitro compound	Pesticide
Furan	110-00-9	Heterocyclic	Chemical intermediate
Gel Cleanser (HZE) 100%	-	Formulation	Surfactant-containing formulation
General Cleaner (#11)	-	Formulation	Cleaner
General Cleaner (#12)	-	Formulation	Cleaner
Glass Cleaner (#19)	-	Formulation	Cleaner
Gluconolactone	90-80-2	Carboxylic acid, Lactone, Carbohydrate	Food additive
DL-Glutamic acid	19285-83-7	Amino acid	Not classified
Glycerol	56-81-5	Alcohol	Solvent; Plasticizer; Lubricant; Emollient; Drug vehicle
3-Glycidoxypropyltrimethoxysilane	2530-83-8	Organosilicon compound	Adhesive
Hand Soap (HZU) 25%	-	Formulation	Surfactant-containing formulation
Heavy Duty Cleaner (#15)	-	Formulation	Cleaner
Heavy Duty Cleaner/Degreaser (#9)	-	Formulation	Cleaner

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Hexadecyltrimethylammonium bromide	57-09-0	Organic salt, Onium compound	Agricultural chemical; Germicide; Drug/Therapeutic agent
1,5-Hexadiene	592-42-7	Hydrocarbon (acyclic)	Not classified
Hexane	110-54-3	Hydrocarbon (acyclic)	Solvent
n-Hexanol	111-27-3	Alcohol	Solvent; Chemical intermediate; Synthetic flavor ingredient
Imidazole	288-32-4	Heterocyclic	Anti-fungal; Enzyme inhibitor
Iminodibenzyl	494-19-9	Heterocyclic	Personal care product
Isobutanol	78-83-1	Alcohol	Solvent; Chemical intermediate; Flavor ingredient
Isopropanol	67-63-0	Alcohol	Solvent; Aerosol formulations (ingredient)
N-Lauroylsarcosine, sodium salt	7631-98-3	Amide, Amino acid (salt)	Surfactant (anionic)
Laurylsulfobetaine	14933-08-5	Amine, Onium compound	Detergent, Surfactant (zwitterionic)
Liquid Soap No. 2 (HZW) 25%	-	Formulation	Surfactant-containing formulation
Liquid Soap No. 1 (HZB) 25%	-	Formulation	Surfactant-containing formulation
Magnesium carbonate	56378-72-4	Inorganic salt	Chemical intermediate
Maneb	12427-38-2	Amine/Amidine, Organic salt, Urea compound	Pesticide
Meat Room Degreaser (#3)	-	Formulation	Degreaser
2-Mercaptopyrimidine	1450-85-7	Acyl halide	Anti-infective; Anti-fungal; Preservative
Metal Cleaner (#20)	-	Formulation	Cleaner

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Methanol	67-56-1	Alcohol	Solvent
2-Methoxyethanol	109-86-4	Alcohol	Solvent; Plasticizer
Methyl acetate	79-20-9	Ester	Solvent; Chemical intermediate; Synthetic flavor ingredient
Methyl cyanoacetate	105-34-0	Ester, Nitrile compound	Adhesive; Pharmaceutical intermediate
Methyl cyclopentadiene dimer	-	Cyclic hydrocarbon	Solvent/industrial chemical; Petrochemical product
Methylcyclopentane	96-37-7	Ketone	Solvent; Manufacture of lacquers, varnishes, cosmetics, pharmaceuticals
Methyl ethyl ketone	78-93-3	Ketone	Solvent; Manufacture of lacquers, varnishes, cosmetics, pharmaceuticals
Methyl isobutyl ketone	108-10-1	Ketone	Solvent; Synthetic flavor; Drycleaning
1-Methylpropyl benzene	135-98-8	Hydrocarbon (cyclic)	Not classified
Mild Shampoo (HZJ) 25%	-	Ketone	Solvent; Synthetic flavor; Drycleaning
MYRJ-45	-	Ketone	Solvent; Manufacture of lacquers, varnishes, cosmetics, pharmaceuticals
1-Naphthalene acetic acid	86-87-3	Carboxylic acid, Polycyclic compound	Pesticide
1-Naphthalene acetic acid, Na salt	61-31-4	Carboxylic acid (salt), Polycyclic compound	Pesticide
1-Nitropropane	108-03-2	Hydrocarbon (acyclic), Nitro compound	Solvent, Chemical intermediate
n-Octanol	111-87-5	Alcohol	Solvent; Fragrance
Parafluoraniline	371-40-4	Amine/Amidine	Intermediate for herbicides; Dyes
2,4-Pentanedione	123-54-6	Ketone	Solvent; Plasticizer

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Petroleum ether	8032-32-4	Hydrocarbon (acyclic)	Solvent
Petroleum wax	-	Wax	Petrochemical product
Phenylbutazone	50-33-9	Heterocyclic	Pharmaceutical
1-Phenyl-3-pyrazolidone	92-43-3	Heterocyclic	Photographic agent
Polishing Scrub (HZT) 100%	-	Formulation	Surfactant-containing formulation
Polyalkenylsuccinate ester/amine salt	-	Amidine	Lubricant additive; Petrochemical product
Polyethylene glycol 400	25322-68-3	Alcohol, Polyether	Surfactant (nonionic), Lubricant, Plasticizer, Solvent
Polyethylene glycol 600	-	Alcohol, Polyether	Surfactant (nonionic)
Pot and Pan Cleaner (#8)	-	Formulation	Cleaner
Potassium cyanate	590-28-3	Inorganic salt	Herbicide; Pharmaceutical intermdiate
Process oil	-	Oil	Petrochemical product
Promethazine hydrochloride	58-33-3	Amine/Amidine, Heterocyclic, Organic sulfur compound	Antihistamine; Anti-nausea drug
Propylene glycol	57-55-6	Alcohol	Solvent
Propyl-4-hydroxybenzoate	94-13-3	Carboxylic acid, Phenol	Antimicrobial
Pyridine	110-86-1	Heterocyclic	Solvent; Intermediate for pharmaceuticals, dyes, pesticides
Quinacrine	69-05-6	Heterocyclic	Drug/Therapeutic agent
Shampoo No. 1 (HZC) 25%	-	Formulation	Surfactant-containing formulation

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Shampoo No. 2 (HZX)	-	Formulation	Surfactant-containing formulation
Shampoo No. 3 (HZM) 25%	-	Formulation	Surfactant-containing formulation
Shampoo No. 4 (HZV) 25%	-	Formulation	Surfactant-containing formulation
Shampoo No. 5 (HZD) 25%	-	Formulation	Surfactant-containing formulation
Shampoo No. 6 (HZN) 25%	-	Formulation	Surfactant-containing formulation
Shampoo No. 7 (HZA)	-	Formulation	Surfactant-containing formulation
Shampoo No. 8 (HZG) 25%	-	Formulation	Surfactant-containing formulation
Shower Gel (HZS) 100%	-	Formulation	Surfactant-containing formulation
Skin Cleanser (HZI) 100%	-	Formulation	Surfactant-containing formulation
Sodium hydroxide (1%)	1310-73-2	Alkali	Caustic agent
Sodium hydroxide (10%)	1310-73-2	Alkali	Caustic agent
Sodium lauryl sulfate (15 %)	151-21-3	Carboxylic acid (salt)	Surfactant (anionic); Detergent
Sodium lauryl sulfate (3 %)	151-21-3	Carboxylic acid (salt)	Surfactant (anionic); Detergent
Sodium lauryl sulfate (30 %)	151-21-3	Carboxylic acid (salt)	Surfactant (anionic); Detergent
Sodium oxalate	62-76-0	Carboxylic acid (salt)	Textile finishing; Pyrotechnic, Industrial byproduct
Sodium perborate	10486-00-7	Inorganic salt, Boron compound	Household cleaner; Detergent
Tetraaminopyrimidine sulfate	5392-28-9	Amine, Heterocycle, Inorganic salt	Not classified

Chemical and Product Classes of Substances Tested in the BCOP Assay

Substance	CASRN[1]	Chemical Class	Product Class
Thiadiazole alkyl derivative	-		Lubricant additive; Petrochemical product
Thiourea	62-56-6	Organic sulfur compound	Photographic agent; Flame-retardant; Chelation reagent and catalyst; Chemical
Toilet Bowl Cleaner (#1)	-	Formulation	Cleaner
Toilet Bowl Cleaner (#4)	-	Formulation	Cleaner
Toluene	108-88-3	Hydrocarbon (cyclic)	Solvent
Trichloroacetic acid (3%)	76-03-9	Carboxylic acid	Caustic agent; Fixative; Herbicide
Trichloroacetic acid (30%)	76-03-9	Carboxylic acid	Caustic agent; Fixative; Herbicide
1,2,3-Trichloropropane	96-18-4	Hydrocarbon (halogenated)	Solvent
Triethanolamine	102-71-6	Amine, Alcohol	Antimicrobial, Chemical intermdiate
1,2,4-Trimethylbenzene	95-63-6	Hydrocarbon (cyclic)	Chemical intermediate
Triton X-100 (1%)	9002-93-1	Ether	Surfactant (nonionic)
Triton X-100 (10 %)	9002-93-1	Ether	Surfactant (nonionic), Detergent, Emulsifier
Triton X-100 (5%)	9002-93-1	Ether	Surfactant (nonionic)
Triton X-155	9010-44-0	Ether	Surfactant (nonionic)
Tween 20	9005-64-5	Ester, Polyether	Surfactant (nonionic); Detergent
Xylene	1330-20-7	Hydrocarbon (cyclic)	Agricultural chemical

[1] CASRN = Chemical Abstracts Service Registry Number

Components of Formulations Tested in Gettings et al. (1996)

Formulation	Formulation Components	% (W/W)
HZA-Shampoo No. 7	Water	53.86
	Sodium lauryl sulfate (30%)	25.00
	Disodium laureth sulfocuccinate (40%)	15.00
	Lauramide DEA	0.50
	Butylene glycol	5.00
	Methyl and propylparabens	0.25
	Carageenan	0.35
	Methyl and methylchloroisothiazolinone	0.04
HZB-Liquid Soap No. 1	Water and volatiles	65-85
	Ammonium lauryl sulfate	1-10
	Sodium laureth sulfate	1-10
	Lauramide DEA	1-10
	Glycerine	1-10
	Isostearamidopropyl morpholine lactate	0.1-1.0
	Disodium ricinoleamido MEA-sulfosuccinate	0.1-1.0
	DMDM hydantoin	0.1-1.0
	Citric acid	0.1-1.0
	Triclosan	0.1-1.0
	Tetrasodium EDTA	<0.1
	FD&C Yellow No. 5	<0.1
	FD&C Red No. 4	<0.1
HZC-Shampoo No. 1	Water	14.037
	Laurylamidopropyl betaine (30%)	60.000
	Cetrimonium chloride	16.000
	PEG-3 cocamide	4.500
	Citric acid	3.500
	Sodium chloride	1.000
	Ditallowdimonium chloride (73%)	0.700
	Lauryl alcohol	0.250
	Methyl and chloroisothiazolinone (1.5%)	0.033

Components of Formulations Tested in Gettings et al. (1996)

Formulation	Formulation Components	% (W/W)
HZD-Shampoo No. 5	Water	54.120
	Sodium laureth sulfate (26%)	38.00

Annex I-5

Components of AMCP Formulations Tested

This page intentionally left blank

Components of AMCP Formulations Tested

Formulation Name	Formulation Components	Percentage
A, Disinfectant/Cleaner Concentrate	Water	65-70
	Inorganic Salt	1-5
	Inorganic Phosphate	1-5
	Quaternary	1-5
	Nonionic Surfactant	1-5
	pH adjuster	<1
	Chelator	<1
	Fragrance	<1
	Dyes	<1
B, Disinfectant/Cleaner Concentrate	Water	60-65
	Fragrance	<1
	Dye	<1
	Quaternary	15-20
	Chelator	1-5
	Inorganic Salt	1-5
	Nonionic Surfactant	1-5
C, Disinfectant/Cleaner Concentrate	Water	75-80
	Hydrogen Peroxide	5-10
	Solvent	1-5
	Anionic Surfactant	1-5
	Inorganic Alkalis	1-5
	Organic Acid	1-5
	Corrosion Inhibitors	1-5
	Organic Acid	1-5
	Nonionic Surfactant	<1
	Inorganic Salt	<1
	Inorganic Salt	<1
	Inorganic Acid	<1
	Organic Acid	<1
	Organic Acid	<1
	Organic Acid	1-5
D, Stone Floor Polish	Water	60-65
	Organic Acid	30-35
	Thickeners	5-10
	Plasticizers	<1
E, Disinfectant/Cleaner Concentrate	Water	75-80
	Ouaternary	1-5
	Inorganic Phosphates	1-5
	Inorganic Salt	1-5
	Nonionic Surfactant	1-5
	pH adjuster	<1
	Chelator	<1
	Fragrance	<1
	Dye	<1
F, Disinfectant/Cleaner Concentrate	Water	60-65
	Inorganic Acid	1-5
	Organic Acid	5-10
	Anionic Surfactant	1-5
	Organic Acid	<1
	Corrosion Inhibitor	<1
	Nonionic Surfactant	1-5
	Solvent	5-10
	Fragrance	<1

Components of AMCP Formulations Tested

Formulation Name	Formulation Components	Percentage
	Hydrogen Peroxide	1-5
G, Disinfectant/Cleaner Concentrate	Water	40-50
	Solvent	25-35
	Chelator	1-5
	Amine	5-10
	Quaternary	1-5
	Nonionic Surfactant	10-15
	Fragrance	1-5
	Dyes	<1
H, Disinfectant/Cleaner Concentrate	Water	90-95
	Solvent	1-5
	Inorganic Phosphates	1-5
	Nonionic Surfactant	<1
	Inorganic Alkalis	<1
	Quaternary	<1
	Inorganic Salt	<1
	Fragrance	<1
	Nonionic Surfactant	<1
	Thickeners	<1
I, Disinfectant/Cleaner RTU	Water	95-100
	Inorganic Salt	<1
	Inorganic Phosphate	<1
	Quaternary	<1
	Nonionic Surfactant	<1
	pH adjuster	<1
	Chelator	<1
	Fragrance	<1
	Dyes	<1
J, Disinfectant/Cleaner RTU	Water	90-95
	Solvent	1-5
	Nonionic Surfactant	1-5
	pH adjuster	<1
	Fragrance	<1
	Quaternary	<1
	Amine	<1
	Thickeners	<1
	Dye	<1
K, Disinfectant	Water	95-100
	Inorganic Salt	<1
	Anionic Surfactant	<1
	TCM	<1
	pH adjuster	<1
L, Disinfectant/Cleaner RTU	Water	95-100
	Fragrance	<1
	Dye	<1
	Quaternary	<1
	Chelator	<1
	Inorganic Salt	<1
	Nonionic Surfactant	<1

Components of AMCP Formulations Tested

Formulation Name	Formulation Components	Percentage
M, Disinfectant/Cleaner RTU	Water	85-90
	Solvent	5-10
	Chelator	1-5
	Nonionic Alkoxylate	<1
	Quaternary	<1
	Inorganic Salt	<1
	Fragrance	<1
N, Disinfectant/Cleaner Concentrate	Water	70-75
	Nonionic Surfactant	5-10
	Nonionic Surfactant	5-10
	Hydrotrope	5-10
	Chelator	<1
	pH adjuster	<1
	Hydrogen Peroxide	1-5
O, Disinfectant/Cleaner Concentrate	Water	95-100
	Quaternary	<1
	Nonionic Alkoxylate	<1
	Chelator	<1
	Inorganic Salt	<1
	Fragrance	<1
	Dye	<1
P, Disinfectant/Cleaner RTU	Water	95-100
	Phenolics	<1
	Anionic Surfactant	<1
	Solvent	<1
	Chelator	<1
	pH adjuster	<1
	Solvent	<1
	Anionic Surfactant	<1
	Antioxidants	<1
	Inorganic Salts	<1
	Fragrance	<1
	Dye	<1
Q, Disinfectant/Cleaner	Water	95-100
	Nonionic Surfactant	<1
	Fragrance	<1
	Solvent	<1
	pH adjuster	<1
	Quaternary	<1
R, Disinfectant	Water	95-100
	Quaternary	<1
	Dye	<1
S, Acid Toilet Bowl Cleaner	Water	90-95
	Inorganic Acid	5-10
	Anionic Surfactant	1-5
	Inorganic Salts	<1
	Dye	<1
T, Descaler	Water	75-80
	Inorganic Acid	10/15
	pH adjuster	1-5

Components of AMCP Formulations Tested

Formulation Name	Formulation Components	Percentage
U, Disinfectant/Cleaner RTU	Water	95-100
	Quaternary	<1
	Inorganic Phosphates	<1
	Inorganic Salt	<1
	Nonionic Surfactant	<1
	pH adjuster	<1
	Chelator	<1

V, Disinfectant/Cleaner RTU	Water	95-100
	Solvent	1-5
	Chelator	<1
	Amine	<1
	Quaternary	<1
	Nonionic Surfactant	<1
	Fragrance	<1
	Dyes	<1
W, Disinfectant RTU	Water	95-100
	Quaternary	<1
	Fragrance	<1
AB (active ingredient)	Alkyl (60% C14, 30% C16, 5% C12, 5% C18) Dimethyl Benzyl Ammonium Chloride	3%
AF, Disinfectant (active ingredient)	Octanoic Acid	0.138%
AG, Metal Cleaner	Water	65-70
	Chelator	5-10
	NaOH	5-10
	Nonionic Surfactant	5-10
	KOH	<1
AH, Degreaser	Water	65-70
	Anionic Surfactant	5-10
	Chelator	5-10
	Nonionic Surfactant	5-10
	KOH	1-5
	Inorganic Salt	1-5
	Glycol Ether	1-5
AI, Heavy Duty Cleaner/Degreaser	Water	75-80
	Inorganic Salts	10-15
	Chelator	1-5
	NaOH	1-5
	Nonionic Surfactant	1-5
	Amphoteric Surfactant	1-5
	Dye	<1
AJ, Heavy Duty Cleaner	Water	65-70
	Inorganic Salts	10-15
	Anionic Surfactant	5-10
	Chelator	1-5
	NaOH	1-5
	Nonionic Surfactant	1-5
	Amphoteric Surfactant	1-5

Components of AMCP Formulations Tested

Formulation Name	Formulation Components	Percentage
AK, Floor Stripper	Water	55-60
	Glycol Ether	10-15
	Inorganic Salt	5-10
	Amphoteric Surfactant	5-10
	MEA	1-5
	NaOH	1-5
	Chelator	1-5
	Nonionic Surfactants	<1
	Fragrance	<1
AL, Cleaner/Degreaser	Water	65-70
	Glycol Ether	10/15
	Anionic Surfactant	1-5
	Inorganic Salt	1-5
	Chelator	1-5
	Nonionic Surfactant	5-10
	NaOH	1-5
	Dye	<1
AM, Glass Cleaner	Water	65-70
	Glycol Ether	20-25
	Ammonium Hydroxide	1-5
	Anionic Surfactant	1-5
	Chelator	1-5
	Dye	<1
AN, General Cleaner	Water	75-80
	Anionic Surfactant	10-15
	Nonionic Surfactant	5-10
	Chelator	1-5
	Inorganic Salt	1-5
AO, Floor Stripper	Water	60-65
	Glycol Ether	10-15
	Anionic Surfactant	10-15
	MEA	5-10
	Organic Solvent	1-5
	Inorganic Salt	1-5
	NaOH	1-5
	Chelator	<1
	Flurochemical	<1
	Fragrance	<1
AP, All Purpose Cleaner	Water	80-85
	Inorganic Salt	5-10
	NaOH	1-5
	Nonionic Surfactant	1-5
	Anionic Surfactant	1-5
	KOH	<1
	Chelator	<1

Abbreviations: CASRN=Chemical Abstract Services Registry Number; SCNM=Study Criteria Not Met; n.p.=Not Provided; n.a.=Not Applicable

[1] *In Vitro* Classification represents the BCOP ocular irritancy classification assigned for each chemical in the study for each test for a specific substance

[2] Consensus classification represents the overall BCOP ocular irritancy classification assigned for each chemical in the study based on the majority of ocular irritancy classification calls

[1] *In Vitro* Classification represents the BCOP ocular irritancy classification assigned for each chemical in the study for each test for a specific substance

[2] Consensus classification represents the overall BCOP ocular irritancy classification assigned for each chemical in the study based on the majority of ocular irritancy classification calls

Abbreviations: CASRN = Chemical Abstract Services Registry Number; SCNM = study criteria not met; n.p. = not provided

[1] Consensus classification represents the overall BCOP ocular irritancy classification assigned for each chemical in the study based on the majority of ocular irritancy classification calls

[2] GHS = Globally Harmonized System (UN 2007)

[3] Eye Irritant Category 1 = irreversible effects on the eye/serious damage to the eye; Category 2A = reversible effects on the eye/irritating to the eyes; Category 2B = reversible effects on the eye/mildly irritating to the eyes; Nonirritant = not an eye irritant

[4] EPA = U.S. Environmental Protection Agency (EPA 2003a).

[5] Toxicity Category I for the Primary Eye Irritation Study = corrosive, or corneal involvement or irritation not reversible within 21 days; Category II = corneal involvement or irritation clearing in 8-21 days; Category III = corneal involvement or irritation clearing in 1-7 days; Category IV: minimal effects clearing in less than 24 hr

[6] EU = European Union (EU 2001).

[7] Risk phrase R41 = risk of serious damage to the eyes; R36 = irritating to the eyes; nonirritant = not an eye irritant.

[8] FHSA=Federal Hazardous Substance Act (2005). FHSA-20% is based on the proportion of positive animals needed to identify a substance as an irritant using the FHSA sequential testing strategy, where 20% of the animals need to demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled if ≤ 1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there were ≥1 positive animal in a 3 to 5 animal test or ≥2 positive animals in a 6 animal test.

[9] FHSA=Federal Hazardous Substances Act (2005). FHSA-67% is based on the proportion of positive animals needed to identify a substance as an irritant using the "first test" of the FHSA sequential testing strategy, where 67% of the animals need to demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled if ≤ 1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there were ≥2/3, 3/4, 4/5, or 4/6 positive animals. If 1/3, 1/4, 2/4, 1/5, 2/5, 3/5, 2/6, or 3/6 animals were positive, further testing would be required.

Annex III-2

Comparison of In Vivo and In Vitro Ocular Irritancy Classifications: Sorted by Substance

Substance	CASRN	Form Tested	Concentration Tested	Purity (%)	*In Vitro* Consensus Classification Severe ≥ 55.1[1]	*In Vivo* GHS[2,3]	*In Vivo* EPA[4,5]	*In Vivo* EU[6,7]	FHSA-20%[8]	FHSA-67%[9]	*In Vitro* Consensus Classification Severe ≥ 75[1]	Reference
Tween 20	9005-64-5	liquid	100%	98	Nonirritant	Nonirritant	Category III	Nonirritant	Irritant	Inconclusive	Nonirritant	Southee (1998)
U		n.p.	n.p.	n.p.	Cat III	Nonirritant	Category IV	n.p.	Not labeled	Not labeled	Cat III	AMCP BRD
V		n.p.	n.p.	n.p.	Cat III	Nonirritant	Category IV	n.p.	Not labeled	Not labeled	Cat III	AMCP BRD
W		n.p.	n.p.	n.p.	Cat III	Nonirritant	Category IV	n.p.	Not labeled	Not labeled	Cat III	AMCP BRD
X		n.p.	n.p.	n.p.	Cat I	Category 2A	Category I	n.p.	Irritant	Irritant	Cat I	AMCP BRD
Y		n.p.	n.p.	n.p.	Cat I	Category 2A	Category II	n.p.	Irritant	Irritant	Cat II	AMCP BRD
Z		n.p.	n.p.	n.p.	Cat II	Category 2A	Category II	n.p.	Irritant	Irritant	Cat II	AMCP BRD

Abbreviations: CASRN = Chemical Abstract Services Registry Number; SCNM = study criteria not met; n.p. = not provided

[1] Consensus classification represents the overall BCOP ocular irritancy classification assigned for each chemical in the study based on the majority of ocular irritancy classification calls

[2] GHS=Globally Harmonized System (UN 2007)

[3] Eye Irritant Category 1 = irreversible effects on the eye/serious damage to the eye; Category 2A = reversible effects on the eye/irritating to the eyes; Category 2B = reversible effects on the eye/mildly irritating to the eyes; Nonirritant = not an eye irritant

[4] EPA = U.S. Environmental Protection Agency (EPA 2003a).

[5] Toxicity Category I for the Primary Eye Irritation Study = corrosive, or corneal involvement or irritation not reversible within 21 days; Category II = corneal involvement or irritation clearing in 8-21 days; Category III = corneal involvement or irritation clearing in 1-7 days; Category IV: minimal effects clearing in less than 24 hr

[6] EU=European Union (EU 2001).

[7] Risk phrase R41 = risk of serious damage to the eyes; R36 = irritating to the eyes; nonirritant = not an eye irritant.

[8] FHSA=Federal Hazardous Substance Act (2005). FHSA-20% is based on the proportion of positive animals needed to identify a substance as an irritant using the FHSA sequential testing strategy, where 20% of the animals need to demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled if ≤ 1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there were ≥1 positive animal in a 3 to 5 animal test or ≥2 positive animals in a 6 animal test.

[9] FHSA=Federal Hazardous Substances Act (2005). FHSA-67% is based on the proportion of positive animals needed to identify a substance as an irritant using the "first test" of the FHSA sequential testing strategy, where 67% of the animals need to demonstrate a positive response for a substance to be identified as an irritant. A substance tested using 3 to 6 animals would not be labeled if ≤ 1/6 animals were positive based on the FHSA criteria. The substance would be labeled as an irritant if there were ≥2/3, 3/4, 4/5, or 4/6 positive animals. If 1/3, 1/4, 2/4, 1/5, 2/5, 3/5, 2/6, or 3/6 animals were positive, further testing would be required.

Appendix D

Background Review Document of Existing Methods for Eye Irritation Testing: Silicon Microphysiometer and Cytosensor Microphysiometer
