## Foreword

The National Toxicology Program (NTP), established in 1978, is an interagency program within the Public Health Service of the U.S. Department of Health and Human Services. Its activities are executed through a partnership of the National Institute for Occupational Safety and Health (part of the Centers for Disease Control and Prevention), the Food and Drug Administration (primarily at the National Center for Toxicological Research), and the National Institute of Environmental Health Sciences (part of the National Institutes of Health), where the program is administratively located. NTP offers a unique venue for the testing, research, and analysis of agents of concern to identify toxic and biological effects, provide information that strengthens the science base, and inform decisions by health regulatory and research agencies to safeguard public health. NTP also works to develop and apply new and improved methods and approaches that advance toxicology and better assess health effects from environmental exposures.

The NTP Technical Report series for developmental and reproductive toxicity (DART) studies began in 2019. The studies described in this NTP Technical Report series (i.e., the NTP DART Report series) are designed and conducted to characterize and evaluate the developmental or reproductive toxicity of selected substances in laboratory animals. Substances (e.g., chemicals, physical agents, and mixtures) selected for NTP reproductive and developmental studies are chosen primarily on the basis of human exposure, level of commercial production, and chemical structure. The interpretive conclusions presented in NTP DART Reports are based only on the results of these NTP studies, and extrapolation of these results to other species, including characterization of hazards and risks to humans, requires analyses beyond the intent of these reports. Selection for study per se is not an indicator of a substance's developmental or reproductive toxicity potential.

NTP conducts its studies in compliance with its laboratory health and safety guidelines and the Food and Drug Administration [Good Laboratory Practice Regulations](#) and meets or exceeds all applicable federal, state, and local health and safety regulations. Animal care and use are in accordance with the [Public Health Service Policy on Humane Care and Use of Laboratory Animals](#). Studies are subjected to retrospective quality assurance audits before they are presented for public review. Draft reports undergo external peer review before they are finalized and published.

The NTP DART Reports are available free of charge on the [NTP website](#) and cataloged in [PubMed](#), a free resource developed and maintained by the National Library of Medicine (part of the National Institutes of Health). Data for these studies are included in NTP's [Chemical Effects in Biological Systems](#) database.

For questions about the reports and studies, please email [NTP](#) or call 984-287-3211.

## Explanation of Levels of Evidence for Developmental and Reproductive Toxicity

The National Toxicology Program (NTP) describes the results of individual studies of chemical agents and other test articles and notes the strength of the evidence for conclusions regarding each study. Generally, each study is confined to a single laboratory animal species, although in some instances, multiple species may be investigated under the purview of a single study report. Negative results, in which the study animals do not exhibit evidence of developmental toxicity, do not necessarily imply that a test article is not a developmental toxicant, but only that the test article is not a developmental toxicant under the specific conditions of the study. Positive results demonstrating that a test article causes developmental toxicity in laboratory animals under the conditions of the study are assumed to be relevant to humans, unless data are available that demonstrate otherwise. In addition, such positive effects should be assumed to be primary effects, unless there is clear evidence that they are secondary consequences of excessive maternal toxicity. Given that developmental events are intertwined in the reproductive process, effects on developmental toxicity may be detected in reproductive studies. Evaluation of such developmental effects should be based on the NTP Criteria for Levels of Evidence for Developmental Toxicity.

It is critical to recognize that the “levels of evidence” statements described herein describe only developmental **hazard**. The actual determination of **risk** to humans requires exposure data that are not considered in these summary statements.

Five categories of evidence of reproductive toxicity are used to summarize the strength of the evidence observed in each experiment: two categories for positive results (**clear evidence** and **some evidence**); one category for uncertain findings (**equivocal evidence**); one category for no observable effects (**no evidence**); and one category for experiments that cannot be evaluated because of major design or performance flaws (**inadequate study**). Application of these criteria requires professional judgment by individuals with ample experience with and understanding of the animal models and study designs employed. For each study, conclusion statements are made using one of the following five categories to describe the findings; if warranted, these conclusion statements should be made separately for males and females. These categories refer to the strength of the evidence of the experimental results and not to potency or mechanism.

### Levels of Evidence for Evaluating Reproductive Toxicity

- **Clear evidence** of reproductive toxicity is demonstrated by a dose-related effect on fertility or fecundity, or by changes in multiple interrelated reproductive parameters of sufficient magnitude that by weight of evidence implies a compromise in reproductive function.
- **Some evidence** of reproductive toxicity is demonstrated by effects on reproductive parameters, the net impact of which is judged by weight of evidence to have potential to compromise reproductive function. Relative to clear evidence of reproductive toxicity, such effects would be characterized by greater uncertainties or weaker relationships with regard to dose, severity, magnitude, incidence, persistence, or decreased concordance among affected endpoints.

- 1 • **Equivocal evidence** of reproductive toxicity is demonstrated by marginal or  
2 discordant effects on reproductive parameters that may or may not be related to the  
3 test article.
- 4 • **No evidence** of reproductive toxicity is demonstrated by data from a study with  
5 appropriate experimental design and conduct that are interpreted as showing no  
6 biologically relevant effects on reproductive parameters that are related to the test  
7 article.
- 8 • **Inadequate study** of reproductive toxicity is demonstrated by a study that, because  
9 of major design or performance flaws, cannot be used to determine the occurrence of  
10 reproductive toxicity.

## 11 **Levels of Evidence for Evaluating Developmental System Toxicity**

- 12 • **Clear evidence** of developmental toxicity is demonstrated by data that indicate a  
13 dose-related effect on one or more of its four elements (embryo-fetal death, structural  
14 malformations, growth retardation, or functional deficits) that is not secondary to  
15 overt maternal toxicity.
- 16 • **Some evidence** of developmental toxicity is demonstrated by dose-related effects on  
17 one or more of its four elements (embryo-fetal death, structural malformations,  
18 growth retardation, or functional deficits), but are greater uncertainties or weaker  
19 relationships with regard to dose, severity, magnitude, incidence, persistence, or  
20 decreased concordance among affected endpoints occur.
- 21 • **Equivocal evidence** of developmental toxicity is demonstrated by marginal or  
22 discordant effects on developmental parameters that may or may not be related to the  
23 test article.
- 24 • **No evidence** of developmental toxicity is demonstrated by data from a study with  
25 appropriate experimental design and conduct that are interpreted as showing no  
26 biologically relevant effects on developmental parameters that are related to the test  
27 article.
- 28 • **Inadequate study** of developmental toxicity is demonstrated by a study that, because  
29 of major design or performance flaws, cannot be used to determine the occurrence of  
30 developmental toxicity.

31 When a conclusion statement for a particular study is selected, consideration must be given to  
32 key factors that would support the selection of an individual category of evidence. Such  
33 consideration should allow for incorporation of scientific experience and current understanding  
34 of developmental and reproductive toxicity studies in laboratory animals, particularly with  
35 respect to interrelationships between endpoints or malformation, impact of the change on  
36 reproductive function and/or developmental outcomes, relative sensitivity of endpoints, normal  
37 background incidence, and specificity of the effect. For those evaluations that may be on the  
38 borderline between two adjacent levels, some factors to consider in selecting the level of  
39 evidence of reproductive toxicity are given below:

- 40 • Increases in severity and/or prevalence (more individuals and/or more affected litters)  
41 as a function of dose generally strengthen the level of evidence, keeping in mind that  
42 the specific manifestation may be different with increasing dose. For example,

- 1 histological changes at a lower dose level may reflect reductions in fertility at higher  
2 dose levels.
- 3 • In general, the more animals affected, the stronger the evidence; however, effects on a  
4 small number of animals across multiple related endpoints should not be discounted,  
5 even in the absence of statistical significance for the individual endpoint(s). In  
6 addition, effects with low background incidence when interpreted in the context of  
7 historical controls may be biologically important.
  - 8 • Effects seen in many litters may provide stronger evidence than effects confined to  
9 one or a few litters, even if the incidence within those litters is high.
  - 10 • Because of the complex relationship between maternal physiology and development,  
11 evidence for developmental toxicity may be greater for a selective effect on the  
12 embryo-fetus or pup.
  - 13 • Concordant effects (syndromic) may strengthen the evidence of developmental  
14 toxicity. Single endpoint changes by themselves may be weaker indicators of effect  
15 than concordant effects on multiple endpoints related by a common process or  
16 mechanism.
  - 17 • In order to be assigned a level of “clear evidence” the endpoint(s) evaluated should  
18 normally show a statistical increase in the deficit, or syndrome, on a litter basis.
  - 19 • Consistency of effects across generations may strengthen the level of evidence.  
20 However, special care should be taken for decrements in reproductive parameters  
21 noted in the F<sub>1</sub> generation that were not seen in the F<sub>0</sub> generation, which may suggest  
22 developmental as well as reproductive toxicity. Alternatively, if effects are observed  
23 in the F<sub>1</sub> generation but not in the F<sub>2</sub> generation (or the effects occur at a lesser  
24 frequency in the F<sub>2</sub> generation), this may be due to the nature of the effect resulting in  
25 selection for resistance to the effect (i.e., if the effect is incompatible with successful  
26 reproduction, then the affected individuals will not produce offspring).
  - 27 • Transient changes (e.g., pup weight decrements) by themselves are weaker indicators  
28 of effect than persistent changes.
  - 29 • Single end point changes by themselves are weaker indicators of effect than  
30 concordant effects on multiple, interrelated end points.
  - 31 • Marked changes in multiple reproductive tract endpoints without effects on integrated  
32 reproductive function (i.e., fertility and fecundity) may be sufficient to reach a  
33 conclusion of clear evidence of reproductive toxicity.
  - 34 • Insights from supportive studies (e.g., toxicokinetics, ADME [absorption,  
35 distribution, metabolism, and excretion], computational models, structure-activity  
36 relationships) and reproductive findings from other in vivo animal studies (NTP or  
37 otherwise) should be drawn upon when interpreting the biological plausibility of an  
38 effect.
  - 39 • New assays or techniques need to be appropriately characterized to build confidence  
40 in their utility: their usefulness as indicators of effect is increased if they can be  
41 associated with changes in traditional endpoints.

## Peer Review

1  
2 The National Toxicology Program (NTP) convened a virtual external ad hoc panel to peer review  
3 the draft *NTP Developmental and Reproductive Toxicity Technical Report on the Modified One-*  
4 *Generation Study of 2-Hydroxy-4-methoxybenzophenone (CASRN 131-57-7) Administered in*  
5 *Feed to Sprague Dawley (Hsd:Sprague Dawley® SD®) Rats with Prenatal and Reproductive*  
6 *Performance Assessments in F<sub>1</sub> Offspring* on October 14, 2021. NTP announced the peer-review  
7 meeting in the Federal Register (86 FR 42869, August 5, 2021). The public could view the  
8 proceedings online and opportunities were provided for submission of written and oral public  
9 comments. The selection of panel members and conduct of the peer review were in accordance  
10 with federal policies and regulations. The panel was charged to:

- 11 (1) Review and evaluate the scientific and technical elements of each study and its  
12 presentation.
- 13 (2) Determine whether each study's experimental design, conduct, and findings support  
14 NTP's conclusions under the conditions of each study.

15 NTP carefully considered the panel's recommendations in finalizing the report. The peer-review  
16 report is provided in Appendix D. Other meeting materials are available on the NTP website  
17 (<https://ntp.niehs.nih.gov/go/meeting>).

## Abstract

1  
2 2-Hydroxy-4-methoxybenzophenone (2H4MBP), also known as oxybenzone and  
3 benzophenone-3, is approved by the U.S. Food and Drug Administration for use in sunscreens  
4 and other personal care products in concentrations of <6%, either alone or in combination  
5 formulations, and as an indirect food additive in acrylic and modified acrylic plastics that come  
6 into contact with food. Mechanistic screening studies have shown that 2H4MBP and its  
7 metabolites are capable of activating the estrogen receptor and antagonizing the androgen  
8 receptor to varying degrees. The objective of the present study was to characterize the potential  
9 for 2H4MBP to adversely affect any phase of development, maturation, and ability to reproduce  
10 in Sprague Dawley (Hsd:Sprague Dawley® SD®) rats administered 2H4MBP in 5K96 feed, a  
11 diet low in phytoestrogens, using the National Toxicology Program (NTP) modified one-  
12 generation (MOG) study design. Exposure concentrations were based on a dose range-finding  
13 study that demonstrated 25,000 ppm 2H4MBP did not induce excessive maternal toxicity or  
14 affect parturition, litter size, or pup viability. Exposure concentrations of 3,000, 10,000, and  
15 30,000 ppm were selected; ethinyl estradiol (EE), a synthetic form of estrogen, was included at  
16 0.05 ppm as a positive reference control. 2H4MBP intake by F<sub>0</sub> females in the 3,000, 10,000,  
17 25,000, and 50,000 ppm 2H4MBP groups, based on feed consumption and dietary concentrations  
18 from gestation day (GD) 6 through GD 21, was approximately 215, 695, 2,086, and 6,426 mg  
19 2H4MBP/kg body weight/day (mg/kg/day), respectively; from lactation day (LD) 1 through  
20 LD 14, 2H4MBP intake was approximately 577, 1,858, 4,460, and 12,029 mg/kg/day,  
21 respectively.

### Modified One-Generation Study

22 F<sub>0</sub> exposure began on GD 6 and was continual. At weaning on postnatal day (PND) 28,  
23 F<sub>1</sub> offspring were assigned to either reproductive performance (2/sex/litter), prenatal  
24 (1/sex/litter), or biological sampling (1/sex/litter) cohorts. Upon sexual maturity, F<sub>1</sub> mating and  
25 pregnancy indices were evaluated. In the prenatal cohort, F<sub>2</sub> prenatal development (litter size,  
26 fetal weight, and morphology) was assessed on GD 21. In the reproductive performance cohort,  
27 littering indices, F<sub>2</sub> viability, and growth were assessed until PND 28. The likelihood of  
28 identifying potential 2H4MBP-induced adverse effects (similarity and magnitude thereof) at any  
29 phase of growth or development was increased by examining related endpoints in multiple pups  
30 within a litter throughout life, across cohorts, and across generations.  
31

32 2H4MBP exposure at the tested concentrations did not induce any effects on mating or  
33 pregnancy indices. In the prenatal cohort, exposure to 30,000 ppm was associated with  
34 significantly decreased mean numbers of corpora lutea and F<sub>2</sub> implants and a slightly lower  
35 number of live fetuses on GD 21 than in the control group. In the reproductive performance  
36 cohort, total F<sub>2</sub> mean litter size on PND 0 was also significantly decreased compared to the  
37 control group. 2H4MBP exposure might have affected litter size, although the effect was small in  
38 magnitude. Collectively, given the minimal apparent response that may or may not be a direct  
39 effect of 2H4MBP, this was considered equivocal evidence of an adverse effect on reproductive  
40 performance. EE exposure did not affect F<sub>1</sub> live litter size on PND 0, but significantly decreased  
41 mean number of corpora lutea and total F<sub>2</sub> implants were observed.

42 2H4MBP was associated with lower F<sub>1</sub> and F<sub>2</sub> preweaning and F<sub>1</sub> postweaning mean body  
43 weights. At 30,000 ppm 2H4MBP, preweaning F<sub>1</sub> mean body weights of both males and females  
44 were progressively lower over time, relative to their respective control groups. The response was

1 lessened in F<sub>2</sub> males and even more so in F<sub>2</sub> females. Significantly decreased F<sub>1</sub> postweaning  
2 mean body weights were not associated with concurrent lower feed consumption. The effects on  
3 body weights associated with exposure to 2H4MBP were considered some evidence of  
4 developmental toxicity. 2H4MBP intake by F<sub>0</sub> females in the 3,000, 10,000, and 30,000 ppm  
5 2H4MBP groups, based on feed consumption and dietary concentrations from GD 6 through GD  
6 21 was approximately 205, 697, and 2,644 mg/kg/day, respectively; from LD 1 through LD 13,  
7 2H4MBP intake was approximately 484, 1,591, and 5,120 mg/kg/day, respectively. 2H4MBP  
8 intake by the F<sub>1</sub> generation postweaning (PND 28 through PND 91) in the 3,000, 10,000, and  
9 30,000 ppm groups was approximately 267, 948, and 3,003 mg/kg/day (males) and 287, 983, and  
10 3,493 mg/kg/day (females), respectively. 2H4MBP intake by the adult F<sub>1</sub> females in the 3,000,  
11 10,000, and 30,000 ppm groups was approximately 240, 825, and 2,760 mg/kg/day (GD 0  
12 through GD 21) and 426, 1,621, and 5,944 mg/kg/day (LD 1 through LD 13), respectively.

13 Diaphragmatic hernias were observed at a low incidence in 2H4MBP-exposed animals in both  
14 the F<sub>1</sub> and F<sub>2</sub> generations but were not observed in any control animals. Most of the  
15 diaphragmatic hernias were associated histologically with hepatodiaphragmatic hernias. Low  
16 incidences of diaphragmatic and hepatodiaphragmatic hernias have been reported in control  
17 groups in other NTP MOG studies. Therefore, it is unclear whether the occurrences of  
18 diaphragmatic and hepatodiaphragmatic hernias in both the F<sub>1</sub> and F<sub>2</sub> generations were related to  
19 2H4MBP exposure.

20 2H4MBP did not alter estrogen or androgen-mediated developmental markers, and no gross  
21 lesions were observed at adult necropsy consistent with perturbation of normal estrogen receptor-  
22 or androgen-receptor-mediated development. Expected estrogenic responses were observed in  
23 the EE group. In the 30,000 ppm group, adult weights of male androgen-dependent reproductive  
24 tissues were slightly lower than those of the control males, likely secondary to the apparent  
25 growth retardation, and occurred in the absence of histopathological findings. Sperm and  
26 spermatid counts were not affected by 2H4MBP exposure. The ability of F<sub>1</sub> males in either  
27 cohort to successfully mate, resulting in pregnancy, also was not affected. Unlike findings  
28 reported for in vitro cell models, 2H4MBP had no apparent effect on estrogen receptor- or  
29 androgen-receptor-dependent processes, nor did it affect mating or pregnancy indices.

30 2H4MBP exposure in F<sub>1</sub> rats was associated with higher kidney weights, renal tubule epithelial  
31 regeneration, interstitial chronic active inflammation, renal tubule and pelvic concretions, renal  
32 tubule dilation, papillary necrosis, urothelial hyperplasia, and urothelial ulcers. F<sub>1</sub> females also  
33 displayed renal tubule epithelial degeneration, pelvic dilation, chronic progressive nephropathy,  
34 and mineralization. 2H4MBP-exposed F<sub>1</sub> males and females displayed higher liver weights  
35 relative to their respective control groups. The absolute weight of the adrenal glands was  
36 significantly decreased in the 30,000 ppm female group relative to the control group in the  
37 reproductive performance cohort. Several other decreases in organ weights were not associated  
38 with histological correlates and were considered related to changes in body weights.

39 F<sub>2</sub> fetal findings of hydronephrosis of the kidney and enlarged liver were observed in the  
40 30,000 ppm group. F<sub>2</sub> offspring in the 30,000 ppm group exhibited dilation of the renal pelvis.  
41 The observed fetal, PND 28, and adult necropsy findings were consistent with previously  
42 reported studies that identified the kidney and liver as target tissues of 2H4MBP-mediated  
43 toxicity.

## 1 **Conclusions**

2 Under the conditions of this modified one-generation (MOG) study, there was *equivocal*  
3 *evidence of reproductive toxicity* of 2-hydroxy-4-methoxybenzophenone (2H4MBP) in  
4 Hsd:Sprague Dawley® SD® rats based on a decrease in F<sub>2</sub> litter size in both the prenatal and  
5 reproductive performance cohorts.

6 Under the conditions of this MOG study, there was *some evidence of developmental toxicity* of  
7 2H4MBP in Hsd:Sprague Dawley® SD® rats based on the observed postnatal growth retardation.  
8 The relationship of the increased occurrence of diaphragmatic and hepatodiaphragmatic hernias  
9 in F<sub>1</sub> adults and F<sub>2</sub> pups to 2H4MBP exposure is unclear.

10 Exposure to 2H4MBP was not associated with signals consistent with alterations in estrogenic,  
11 androgenic, or antiandrogenic action. Exposure to 2H4MBP was associated with lower F<sub>1</sub> and  
12 F<sub>2</sub> mean body weights; this effect on body weight contributed to the apparent 2H4MBP-related  
13 decreases in male reproductive organ weights. Mating and littering were not significantly  
14 affected by 2H4MBP exposure. Exposure to 2H4MBP was associated with nonneoplastic kidney  
15 lesions in the F<sub>0</sub>, F<sub>1</sub>, and F<sub>2</sub> generations. Expected estrogenic responses were observed in the  
16 EE group.

17 **Synonyms:** Benzophenone-3; (2-hydroxy-4-methoxyphenyl)-phenylmethanoneoxybenzone;  
18 oxybenzone

**Level of Evidence of Reproductive Toxicity:** Equivocal evidence

**Level of Evidence of Developmental Toxicity:** Some evidence

- 1 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.
- 2 Statistical significance for the vehicle control group indicates a significant trend test.
- 3 \*Statistically significant at  $p \leq 0.05$ ; \*\* at  $p \leq 0.01$ .
- 4 #Statistically significant at  $p \leq 0.05$  in litter-based analysis of fetuses.
- 5 EE = ethinyl estradiol; GD = gestation day; LD = lactation day; PND = postnatal day; [M] = malformation; [V] = variation.
- 6 <sup>a</sup>Body weight results given in grams. Feed consumption results given in grams/animal/day.
- 7 <sup>b</sup>Data are presented as mean  $\pm$  standard error.
- 8 <sup>c</sup>Adjusted based on body weight at weaning.
- 9 <sup>d</sup>Upper row denotes number of affected fetuses (%) and lower row the number of affected litters (%).
- 10 <sup>e</sup>Nonneoplastic lesions were not evaluated in the EE group.

1

## Overview

2 The National Toxicology Program (NTP) has assessed the potential adverse effects of sunscreens  
3 using in vitro and in vivo model systems; the data presented herein are part of that larger effort.  
4 The scope of 2-hydroxy-4-methoxybenzophenone (2H4MBP) studies includes the assessment of  
5 potential endocrine activity in the U.S. Environmental Protection Agency Endocrine Disruptor  
6 Screening Program Phase 1 studies (estrogen- and androgen-receptor binding and activation,  
7 Hershberger and uterotrophic assays, aromatase inhibition, and steroid synthesis inhibition) and  
8 characterization of the potential effects of continuous 2H4MBP exposure over multiple  
9 generations using the NTP modified one-generation study design. In this study, exposure to  
10 2H4MBP in feed began on gestation day (GD) 6. At weaning, 1 and 2 pups/sex/litter were  
11 allocated to prenatal and reproductive performance cohorts, respectively; an additional  
12 1 pup/sex/litter was allocated to the biological sampling cohort. In addition to an assessment of  
13 reproductive performance, F<sub>2</sub> fetal outcomes (GD 21 fetal examinations) were assessed in the  
14 prenatal cohort and the potential effects on parturition and early growth of the F<sub>2</sub> generation were  
15 assessed in the reproductive performance cohort. Internal dose metrics were also assessed.  
16 Apical indicators sensitive to endocrine modulation were measured. The U.S. Food and Drug  
17 Administration's National Center for Toxicological Research (NCTR), in partnership under an  
18 Interagency Agreement, has also examined the effects of maternal and lactational exposure to  
19 2H4MBP on development and reproductive organs in male and female rat offspring and on  
20 transcriptional changes in the testes and prostates of young rats. NCTR is also conducting  
21 fertility, embryo-fetal, and pre- and postnatal rat studies to characterize the potential effects of  
22 2H4MBP exposure. This report complements the International Council for Harmonisation of  
23 Technical Requirements for Pharmaceuticals for Human Use (ICH) S5r2 guideline studies on  
24 2H4MBP conducted by NCTR and allows for the comparison of study designs and outcomes.  
25 NTP previously conducted rat and mouse 2- and 13-week toxicity studies by dermal and oral  
26 routes of exposure and assessed the genotoxic potential of 2H4MBP. Potential effects of  
27 2H4MBP exposure on mouse reproduction were assessed using the Reproductive Assessment by  
28 Continuous Breeding protocol. NTP has also conducted 2-year toxicology and carcinogenesis  
29 studies in rats (including perinatal exposure) and mice using dietary exposure.

## 1 Introduction

2  
3 **Figure 1. 2-Hydroxy-4-methoxybenzophenone (CASRN 131-57-7; Chemical Formula: C<sub>14</sub>H<sub>12</sub>O<sub>3</sub>;**  
4 **Molecular Weight: 228.25)**

5 Synonyms: Benzophenone-3; (2-hydroxy-4-methoxyphenyl)-phenylmethanoneoxybenzene; oxybenzone.

## 6 Chemical and Physical Properties

7 2-Hydroxy-4-methoxybenzophenone (2H4MBP) is an off-white to light-yellow powder with a  
8 melting point of 62°C to 65°C. 2H4MBP is relatively insoluble in water (69 mg/kg at 25°C) and  
9 is readily soluble in most organic solvents. 2H4MBP absorbs ultraviolet (UV) A (320–400 nm)  
10 and UVB (290–320 nm) light and is photostable.<sup>1</sup>

## 11 Production, Use, and Human Exposure

12 2H4MBP is synthesized by condensation of benzoic acid with resorcinol monomethyl ether in  
13 the presence of heat, zinc chloride, and polyphosphoric acid or by the Friedel-Crafts reaction of  
14 benzoyl chloride with 3-hydroxyanisole.<sup>2</sup>

15 2H4MBP is commonly used in sunscreens and other personal care products at concentrations of  
16 up to 6% to protect the user from solar erythema. According to the Environmental Working  
17 Group's Guide to Sunscreens database,<sup>3</sup> 2H4MBP is found in more than 1,000 products,  
18 including beach, sport, and baby sunscreens (619), moisturizers with SPF (150), and lip balms  
19 (109). 2H4MBP is also used as a photostabilizer for synthetic resins and polymers to prevent UV  
20 degradation.<sup>4;5</sup> Exposure can occur when present in acrylic and modified acrylic plastics that  
21 come into contact with food.<sup>6</sup>

22 2H4MBP and its metabolites are typically excreted in urine. A study using National Health and  
23 Nutrition Examination Survey (NHANES) cycle data from 2004 to 2012 demonstrated that more  
24 than 96% of the 10,232 samples (representing all populations) contained measurable urinary  
25 concentrations of 2H4MBP. Creatinine-adjusted urinary least square geometric mean  
26 concentrations ranged from 9 to 17 ng/mL in males, and from 18 to 45 ng/mL in females.  
27 Children and adolescent concentrations ranged from 17 to 27 ng/mL and from 13 to 24 ng/mL,  
28 respectively.<sup>7;8</sup> Higher urinary concentrations of 2H4MBP were observed in non-Hispanic  
29 whites (28 ng/mL) than in Mexican Americans (17 ng/mL) or non-Hispanic blacks (13 ng/mL)  
30 and have been attributed to increased sunscreen use.<sup>9</sup> Higher urinary concentrations in females  
31 have been ascribed to the use of personal care products (e.g., lip balms, cosmetics) that often  
32 contain 2H4MBP.<sup>9</sup>

## 1 **Regulatory Status**

2 2H4MBP is approved by the U.S. Food and Drug Administration (FDA) for use as a sunscreen  
3 when present up to 6%, either alone or in combination formulations and as an indirect food  
4 additive present in acrylic and modified acrylic plastics that come into contact with food.<sup>6; 10</sup>  
5 Section 8(a) of the Toxic Substances Control Act requires manufacturers of 2H4MBP to report  
6 preliminary assessment information concerned with production, exposure, and use to the U.S.  
7 Environmental Protection Agency (EPA). The FDA has drafted a proposed rule, “Sunscreen  
8 Drug Products for Over-the-Counter Human Use.”<sup>10</sup>

## 9 **Absorption, Distribution, Metabolism, and Excretion**

### 10 **Experimental Animals**

11 2H4MBP was well absorbed ( $\geq 63.9\%$ ) following a single oral gavage administration of  
12 [<sup>14</sup>C]2H4MBP (3.01–2,570 mg/kg body weight) in male Fischer 344 (F344)/N rats, with the  
13 administered dose excreted primarily via urine (63.9% to 72.9%) and feces (19.3% to 41.7%) by  
14 72 hours postadministration. The radioactivity remaining in tissues 72 hours after administration  
15 was low (approximately 0.1%) in all dose groups.<sup>11</sup> Following dermal application of 51.6, 204,  
16 and 800  $\mu\text{g}$  [<sup>14</sup>C]2H4MBP (in ethanol) to male rats, the dose was excreted mainly via urine  
17 (32.4%, 39.2%, and 13.2%, respectively) and feces (16.9%, 22.2%, and 9.15%, respectively) by  
18 72 hours postapplication. The dose excreted in urine and feces suggests that the applied dose  
19 absorbed was 49.3%, 61.4%, and 22.4%, respectively, for 51.6, 204, and 800  $\mu\text{g}$  [<sup>14</sup>C]2H4MBP.  
20 When the dose (50  $\mu\text{g}$ ) was applied dermally in a lotion vehicle, the dose absorbed (51.8%) was  
21 similar to that in ethanol with 33.9% and 17.9% of the dose recovered in urine and feces,  
22 respectively.<sup>11</sup>

23 Absorption, distribution, metabolism, and excretion (ADME) were also investigated in male and  
24 female Sprague Dawley rats and B6C3F1/N mice following gavage administration of  
25 [<sup>14</sup>C]2H4MBP.<sup>12</sup> Following a single gavage administration (10, 100, or 500 mg/kg  
26 [<sup>14</sup>C]2H4MBP) in rats, most of the administered dose was excreted in urine (53% to 58%) and  
27 feces (25% to 42%) by 72 hours postadministration with no observable sex difference in  
28 excretion. The radioactivity in urine suggests that  $\geq 53\%$  of the administered dose was absorbed.  
29 Following a single 100 mg/kg gavage dose in male mice, urinary ( $\geq 34\%$ ) and fecal ( $\geq 24\%$ )  
30 excretion was similar to that of rats. Mice excreted a higher percentage (5% to 15%) of the  
31 administered dose as exhaled CO<sub>2</sub>, however, compared to rats (approximately 1%). The retention  
32 of dose in tissues was low at 72 hours ( $< 1\%$ ) in all gavage groups.

33 ADME of 2H4MBP was investigated in Sprague Dawley rats and B6C3F1/N mice at 72 hours  
34 following dermal application of 0.1 or 10 mg/kg [<sup>14</sup>C]2H4MBP formulated in several vehicles.<sup>12</sup>  
35 In male rats, the highest absorption was observed following application in light paraffin oil  
36 (80%). Absorption following application in ethanol, ethanol:coconut oil (1:1), or coconut oil  
37 alone was comparable to paraffin oil (64% to 73%). In contrast, the absorption of 2H4MBP from  
38 the lotion vehicle (olive oil:emulsifying wax:water [15:15:70 v:v:v]) in male (10 mg/kg, 46%)  
39 and female (15 mg/kg, 29%) rats was lower relative to other vehicles. Both male and female  
40 mice absorbed approximately 60%–69% of the 10 mg/kg dose in ethanol or acetone and 37%–  
41 46% of the 10 mg/kg dose when formulated in the lotion vehicle. There was no dose-related  
42 effect on absorption (0.1 versus 10 mg/kg) in either male rats or mice.<sup>12</sup>

1 Kinetics of disposition of 2H4MBP have been investigated in rats in limited studies. Following a  
 2 single gavage dose of 100 mg/kg 2H4MBP in male Sprague Dawley rats, the time ( $T_{max}$ ) to reach  
 3 the maximum plasma concentration,  $C_{max}$  (21.21  $\mu\text{g/mL}$ ) was 3 hours; the elimination of  
 4 2H4MBP in plasma was biphasic with alpha and beta half-lives of 0.88 and 15.9 hours,  
 5 respectively. Of the tissues examined, the liver had the highest concentration of 2H4MBP and  
 6 conjugated 2H4MBP at 6 hours.<sup>13</sup> In another study, following a 100 mg/kg gavage dose in male  
 7 Sprague Dawley rats, similar plasma  $T_{max}$  (2.72 hours) and  $C_{max}$  (21.21  $\mu\text{g/mL}$ ) were observed,  
 8 with an elimination half-life of 4.58 hours.<sup>14</sup> Following a single gavage dose of 10 mg/kg in male  
 9 and female Sprague Dawley rats, plasma  $T_{max}$  and  $C_{max}$  were 6.0 hours and 8.5 ng/mL,  
 10 respectively, for males and 2.3 hours and 2.9 ng/mL, respectively, for females. The plasma  
 11 elimination half-life was 6.4 hours for males and 18.5 hours for females. The bioavailability of  
 12 2H4MBP in male and female rats was <1%, demonstrating extensive first-pass metabolism of  
 13 2H4MBP following gavage administration.<sup>12</sup>

14 Consistent with low bioavailability, 2H4MBP is metabolized via numerous pathways in rodents,  
 15 including demethylation, oxidation, glucuronidation, and sulfation. Products identified in bile  
 16 and/or urine of rodents following administration of 2H4MBP were 2H4MBP,  
 17 2,4-dihydroxybenzophenone (DHB), 2,3,4-trihydroxybenzophenone (THB),  
 18 2,5-dihydroxy-4-methoxybenzophenone (D2H4MBP), and their corresponding glucuronide and  
 19 sulfate conjugates (Figure 2).<sup>11-13; 15</sup> Similar metabolites were also observed in vitro following  
 20 incubation of 2H4MBP with microsomes.<sup>16; 17</sup> 2H4MBP and DHB have been quantified in serum  
 21 from pregnant rats.<sup>18</sup>

22

23 **Figure 2. Metabolism of 2-Hydroxy-4-methoxybenzophenone in Rodents**

24 2H4MBP = 2-hydroxy-4-methoxybenzophenone; D2H4MBP = 2,5-dihydroxy-4-methoxybenzophenone;

25 THB = trihydroxybenzophenone; DHB = dihydroxybenzophenone.

26 \*Indicates glucuronide and sulfate conjugates.

## 1 **Humans**

2 ADME data on 2H4MBP in humans are limited. Human studies with sunscreens have  
3 demonstrated that 2H4MBP is readily absorbed from the skin.<sup>19</sup> A study that used excised human  
4 epidermis in Franz diffusion cells showed that approximately 10% of the dermally applied dose  
5 of 2H4MBP is absorbed.<sup>20</sup> When applied dermally, 2H4MBP and the metabolites DHB and  
6 2,2'-dihydroxy-4-methoxybenzophenone can be detected in serum and are excreted in urine.<sup>21; 22</sup>  
7 A study examining the absorption of 2H4MBP and subsequent irradiation with UVA and UVB  
8 rays demonstrated that participants excreted 1.2%–8.7% (mean 3.7%) of the total applied dose in  
9 urine. 2H4MBP was detected in urine 3–5 days after application. UV irradiation did not affect  
10 the amount of 2H4MBP excreted.<sup>23</sup> Frequency of sunscreen use is also related to urinary  
11 2H4MBP concentrations, with frequent users having much higher urinary concentrations.<sup>24</sup>  
12 2H4MBP has been detected in maternal urine<sup>25</sup> and breast milk.<sup>26; 27</sup> Human geometric mean  
13 maximum plasma concentrations of 2H4MBP have been shown to be approximately 200 ng/mL  
14 when topically applied. This concentration exceeds the FDA guidance of 0.5 ng/mL that would  
15 necessitate the conduct of additional nonclinical toxicity studies.<sup>28</sup>

## 16 **Developmental and Reproductive Toxicity**

### 17 **Models of Endocrine Activity**

18 2H4MBP has been reported to bind to and activate estrogen receptor (ER) alpha (ER $\alpha$ ) with a  
19 median effective concentration (EC<sub>50</sub>) ranging from approximately 3 to 20  $\mu$ M.<sup>29-32</sup> 2H4MBP  
20 can also activate estrogen receptor beta (ER $\beta$ ),<sup>31; 33</sup> and reports indicate that 2H4MBP can act as  
21 ER $\alpha$ , ER $\beta$ , and progesterone receptor antagonists.<sup>31-33</sup> In NTP-sponsored ER binding and  
22 activation studies<sup>34</sup> conducted under OPPTS<sup>a</sup> 890.1250<sup>35</sup> and OPPTS 890.1300,<sup>36</sup> maximal mean  
23 specific binding was >75%, which categorizes 2H4MBP as “not interactive”; however, 2H4MBP  
24 was able to induce a luciferase response, albeit weak (>10%; logEC<sub>50</sub>s of –3.2 and –4.0 M).  
25 2H4MBP acts as an estrogen in stimulating MCF7 cell proliferation (EC<sub>50</sub> of  $3.7 \times 10^{-6}$  M).  
26 2H4MBP has been shown to induce a uterotrophic response (median effective dose [ED<sub>50</sub>] of  
27 1,000–1,500 mg/kg per day) in immature rats,<sup>37</sup> but 2H4MBP did not cause a uterotrophic  
28 response in ovariectomized rats when tested  $\leq 1$  g/kg in an NTP study.<sup>34</sup> 2H4MBP was evaluated  
29 in quantitative (dose-response) high-throughput screening assays by NTP in the Toxicology in  
30 the 21<sup>st</sup> Century (Tox21) program, and activity was observed in assays measuring stimulation of  
31 ER, progesterone receptor, constitutive androstane receptor, pregnane X receptor, retinoic acid  
32 receptor, and estrogen-related receptor signaling pathways. In addition, 2H4MBP was shown to  
33 inhibit androgen-receptor signaling  
34 ([https://pubchem.ncbi.nlm.nih.gov/compound/4632#section=BioAssay-  
35 Results&fullscreen=true](https://pubchem.ncbi.nlm.nih.gov/compound/4632#section=BioAssay-Results&fullscreen=true)).

36 2H4MBP exposure in male rainbow trout and Japanese medaka has been shown to induce  
37 vitellogenin production (an estrogenic response), decrease the number of eggs produced, and  
38 reduce egg viability and hatching.<sup>38</sup> 2H4MBP has also been shown to increase plasma

---

<sup>a</sup>Guidelines issued before April 22, 2010, refer to “OPPTS” because the office name changed from “Office of Prevention, Pesticides and Toxic Substances” to “Office of Chemical Safety and Pollution Prevention” (or “OCSPP”).

1 concentrations of testosterone in male adult Japanese medaka and to decrease the estradiol-  
2 to-testosterone ratio in both male and female fish with concomitant downregulation of gonadal  
3 steroidogenic genes (*star*, *cyp11a*, *cyp17*, *hsd3b*, *hsd17b3*, and *cyp19a*).<sup>39</sup>

#### 4 **Experimental Animals**

5 The effects of 2H4MBP exposure on sperm density and vaginal cytology have been reported.<sup>40</sup>  
6 Rats and mice received 0, 3,125, 12,500, or 50,000 ppm in the diet for 90 days. Male rats  
7 exposed to 50,000 ppm weighed 30% less than control animals, displayed lower epididymis and  
8 caudal epididymis weights (17% and 22%, respectively), and lower sperm density (27%).  
9 Females displayed a slight increase in estrous cycle length (>1 day) in the 12,500 and  
10 50,000 ppm groups. Male mice in the 50,000 ppm group displayed a 27% decrease in sperm  
11 density and weighed 16% less than control animals. Female mice in the 50,000 ppm group  
12 displayed a slight increase in estrous cycle length relative to control animals (>0.5 days). NTP  
13 conducted a Reproductive Assessment by Continuous Breeding (RACB) study in mice at  
14 exposure concentrations of 12,500, 25,000, or 50,000 ppm in the diet.<sup>41</sup> 2H4MBP exposure had  
15 no effect on F<sub>0</sub> fertility, but the number of live pups per litter was significantly reduced in the  
16 25,000 and 50,000 ppm groups, which was associated with lower parental mean body weights.  
17 There were no changes in sperm density or estrous cyclicity; however, the cumulative days to  
18 litter were increased in the 50,000 ppm group. 2H4MBP had minimal effects on fertility in the  
19 F<sub>1</sub> generation, but pup weights were significantly decreased relative to the control group.  
20 Collectively, the studies indicated that 2H4MBP caused systemic toxicity but had minimal  
21 effects on fertility and reproduction at the exposure concentrations used. Another study  
22 examined the effects of 0, 10, 20, 100, or 400 mg/kg of 2H4MBP dermally applied to mice  
23 5 days per week for 13 weeks. No effects on mean body weight, organ weights, sperm density, or  
24 testicular histopathology were attributed to 2H4MBP exposure.<sup>42</sup>

25 The effects of maternal and lactational exposure to 2H4MBP on F<sub>1</sub> development and  
26 reproductive organs have been assessed.<sup>18</sup> Rats received 0, 1,000, 3,000, 10,000, 25,000, or  
27 50,000 ppm 2H4MBP in the diet from gestation day (GD) 6 until weaning on postnatal day  
28 (PND) 23. Exposure to 2H4MBP was associated with increased liver and kidney weights in  
29 dams. Clinical pathology findings in dams assessed on GDs 10, 15, and 20 and lactation day 23  
30 included elevation of glucose, alanine aminotransferase, alkaline phosphatase, cholesterol, and  
31 total bile acids, as well as depression of aspartate aminotransferase, blood urea nitrogen, and  
32 creatinine. These findings occurred primarily in the higher dosed groups and often at all time  
33 points. Alanine aminotransferase and cholesterol were elevated in the male and female offspring  
34 at the 25,000 and 50,000 ppm exposure concentrations. No significant differences were observed  
35 in littering parameters. Male and female pups in the 25,000 and 50,000 ppm groups displayed  
36 lower body weights than control pups. Male anogenital distance, adjusted for body weight at  
37 PND 23, was significantly decreased in the 50,000 ppm group relative to the control group. At  
38 necropsy on PND 23, relative female liver weights were higher than those of the control group at  
39 exposure concentrations ≥10,000 ppm. In the 50,000 ppm group, spermatocyte development was  
40 impaired and ovarian follicular development was delayed.

#### 41 **Endocrine Disruptor Screening Panel Studies**

42 The potential for 2H4MBP to bind to the ER was assessed in accordance with EPA guideline  
43 OPPTS 890.1250.<sup>35</sup> In each of three independent experiments, the maximal mean specific

1 binding was >75% at every soluble 2H4MBP concentration assessed, thereby categorizing  
2 2H4MBP as “not interactive.” When the specific binding was averaged using the scoring system  
3 as described in the OPPTS guideline, 2H4MBP was classified as “not interactive” with a median  
4 inhibitory concentration (IC<sub>50</sub>) of approximately  $2.3 \times 10^{-4}$  to  $14.8 \times 10^{-4}$  M. In the ER  
5 transcriptional activation assay, conducted in accordance with EPA guideline  
6 OPPTS 890.1300,<sup>35</sup> 2H4MBP at  $10^{-5}$  M induced relative luciferase activity of 14.9% and 20.9%  
7 in each respective run. 2H4MBP was considered a “positive” agent, per OPPTS 890.1300,  
8 because it exceeded 10% of the response of the positive control. 2H4MBP was assessed in a  
9 uterotrophic assay in accordance with OPPTS 890.1600,<sup>35</sup> and 2H4MBP did not significantly  
10 alter uterine wet or blotted weights.<sup>34</sup>

11 The potential for 2H4MBP to bind to the rat androgen receptor was assessed in accordance with  
12 OPPTS 890.1150.<sup>35</sup> 2H4MBP tested up to  $10^{-4}$  M did not displace more than 50% of the  
13 [<sup>3</sup>H]-R1881, a synthetic androgen-receptor agonist, categorizing 2H4MBP as “equivocal.” The  
14 potential for 2H4MBP to induce androgenic agonist and antagonist transactivation activity was  
15 assessed in MDA-kb2 reporter cells that had been stably transfected with a mouse mammary  
16 tumor virus luciferase-neo reporter construct containing the androgen response element. In all  
17 independent runs of the agonist transcriptional activation assay, 2H4MBP did not increase in  
18 luciferase activity at any of the viable soluble concentrations tested. In two of three runs, the  
19 decrease in dihydrotestosterone-induced luciferase activity resulting from 2H4MBP exposure  
20 was approximately 25% at the highest feasible dose of  $10^{-4.5}$  M, with the first run exhibiting a  
21 luciferase activity of 72.2% of maximal. The potential for 2H4MBP to have an androgenic or  
22 antiandrogenic response was assessed in a Hershberger bioassay conducted in accordance with  
23 OPPTS 890.1400.<sup>35</sup> In the absence of androgenic action, 2H4MBP up to 1,000 mg/kg did not  
24 have any effect on androgen-dependent organ weights, demonstrating that 2H4MBP does not  
25 exhibit any in vivo androgenic activity in this model system. Rats co-administered 1,000 mg/kg  
26 of 2H4MBP and testosterone propionate displayed significantly decreased day 10 mean body  
27 weight and body weight gain (7% and 28%, respectively) relative to the control group. The mean  
28 weights of the glans penis and ventral prostate were also significantly decreased (6% and 20%,  
29 respectively). The weight of the seminal vesicles was also significantly decreased; however,  
30 when concurrent body weight is used as a covariate, the magnitude of the response is lower and  
31 no longer attains statistical significance. The fact that these organ weight changes only occurred  
32 in the presence of lower body weights at the highest dose assessed suggests that they could be  
33 secondary to effects on body weight.<sup>34</sup>

34 The potential for 2H4MBP to act as an inhibitor of aromatase activity was assessed using human  
35 CYP19 (aromatase) and P450 reductase Supersomes™ 2H4MBP in accordance with  
36 OPPTS 890.1200.<sup>35</sup> 2H4MBP was classified as equivocal, as it produced a mean aromatase  
37 activity level of 51% ( $\pm 13\%$  SD) of control activity at the highest soluble test concentration of  
38  $10^{-4}$  M.<sup>34</sup>

## 39 **Humans**

40 Maternal 2H4MBP exposure, determined primarily via third trimester urinary concentrations,  
41 was associated with lower birth weight of girls and higher birth weight of boys.<sup>43</sup> In another  
42 study, maternal gestational urinary 2H4MBP concentrations were positively associated with  
43 weight and head circumference at birth in male newborns.<sup>44</sup> Maternal exposure to 2H4MBP has  
44 been postulated to be involved in the development of Hirschsprung’s disease. One hypothesis is

1 that this complex congenital disease is caused by gene–environment interactions that can lead to  
2 intestinal obstruction and chronic constipation in the offspring.<sup>45</sup> Pregnant women who had  
3 higher 2H4MBP concentrations in urine exhibited higher odds (2.4 to 2.6:1) of having a child  
4 with Hirschsprung’s disease.<sup>25</sup> In the 293T and SH-SY5Y cell migration model of  
5 Hirschsprung’s disease, 2H4MBP suppressed migration and altered the levels of key migratory  
6 proteins at both the ribonucleic acid and transcribed protein levels in the absence of  
7 cytotoxicity.<sup>25; 45</sup>

8 A study looking at the potential effect of 2H4MBP dermal application and serum hormone  
9 changes in young men and postmenopausal women concluded that the amount of 2H4MBP  
10 absorbed did not alter the endogenous reproductive hormone homeostasis.<sup>19</sup>

## 11 **General Toxicity**

### 12 **Experimental Animals**

13 The acute rat dermal median lethal dose (LD<sub>50</sub>) has been reported to be >16 g/kg. Concomitant  
14 local skin reactions consisting of mild to moderate erythema were observed in the absence of  
15 significant pathological findings.<sup>5</sup> The acute rat oral LD<sub>50</sub> for 2H4MBP has been reported to be  
16 >12.8 g/kg.<sup>46</sup> These authors also reported that administration of 0.5% or 1% 2H4MBP in rat diet  
17 for 12 weeks was associated with growth depression. Upon examination at week 6, female rats  
18 exposed to 0.5% or 1% displayed a leukocytosis with an increase in the lymphocyte count and a  
19 decrease in the neutrophil count, as well as a decrease in hemoglobin concentration compared to  
20 control females. At week 12, exposed rats displayed anemia and lymphocytosis with a reduction  
21 in granulocytes. The relative weights of the pituitary gland, thymus, heart, adrenal gland, lung,  
22 and spleen were also lower in both sexes. The 0.5% females showed higher relative thyroid  
23 weight than the control group, as well as the first stages of kidney degeneration. Degenerative  
24 nephrosis was diagnosed both macro- and microscopically in the kidneys of both sexes at 1%.

25 NTP has reported the findings of three studies conducted in F344 rats exposed to: (1) 0, 3,125,  
26 6,250, 12,500, 25,000, or 50,000 ppm 2H4MBP in feed for 2 or 13 weeks; (2) 0, 1.25, 2.5, 5, 10,  
27 or 20 mg/kg 5 days per week for 2 weeks dermally in acetone or lotion; and (3) 12.5, 25, 50, 100,  
28 or 200 mg/kg in acetone or lotion 5 days per week for 13 weeks.<sup>40</sup> After dietary administration  
29 for 2 weeks, 6,250 ppm 2H4MBP and higher concentrations were associated with higher liver  
30 weights and marked hepatocyte cytoplasmic vacuolization. As was observed in the 2-week study,  
31 kidney and liver weights were higher in the 2H4MBP-exposed rats in the 13-week study at  
32 exposure concentrations of 3,125 ppm and higher (liver) or 25,000 ppm and higher (kidney).  
33 Histopathological kidney findings included dilated tubules and tubular epithelial cell  
34 regeneration. These findings were observed primarily in high-dosed rats. In the 13-week feed  
35 study, 2H4MBP administration was associated with lower body weight gains of 50,000 ppm  
36 male and female rats. Additionally, in the 13-week feed study, kidney lesions progressed to  
37 include papillary degeneration or necrosis and inflammation. Although cytoplasmic  
38 vacuolization was not observed in the liver, liver enzymes remained elevated at 13 weeks. In the  
39 2-week dermal study, small and variable increases in liver and kidney weights were observed in  
40 exposed groups, with statistically significant differences observed primarily in the higher dose  
41 groups. In the 13-week dermal study, female rats in the higher dose groups displayed higher  
42 kidney weights than the control group. No other findings were attributed to 2H4MBP exposure.  
43 A 4-week dermal study in rats using 100 mg/kg 2H4MBP in petroleum jelly twice a day did not

1 affect body weight; liver, kidney, or testes weights; or histopathology.<sup>15</sup> 2H4MBP exposure did  
2 lower rat blood glutathione-S-transferase levels.

### 3 **Humans**

4 The literature contains no studies on the general toxicity of 2H4MBP in humans.

### 5 **Immunotoxicity**

#### 6 **Experimental Animals**

7 A study conducted for irritation per the Draize method concluded that an occlusive patch  
8 containing 0.5 mL or 0.5 mg at 2H4MBP concentrations from 4% to 100% was nonirritating to  
9 intact and abraded albino rabbit skin.<sup>5</sup> 2H4MBP at 100% up to 100 mg was found not to be  
10 irritating to the rabbit eye using the modified FSLA or Draize methods. A sunscreen containing  
11 6% 2H4MBP was found not to be photosensitizing in albino rabbits and was negative for  
12 sensitization potential in the Klingman Maximization Procedure<sup>5</sup> and local lymph node assay.<sup>47</sup>

#### 13 **Humans**

14 Some reports have indicated that 2H4MBP might induce allergenic and sensitization responses.<sup>5</sup>  
15 In a sunscreen sensitization study, researchers detected allergy and/or photoallergy in 3.7% of  
16 the human subjects, which was attributed to application of moisturizing creams that contained  
17 2H4MBP.<sup>48</sup> A subsequent study sponsored by Schering-Plough HealthCare Products reported the  
18 results of the meta-analysis of 64 unpublished studies conducted at 10 independent clinical  
19 laboratories representing the results of 19,570 individuals subjected to human repeat insult patch  
20 tests and photoallergy studies between 1992 and 2006.<sup>49</sup> These studies were aggregated and  
21 analyzed to evaluate the irritancy and sensitization potential of sunscreen products containing  
22 2H4MBP concentrations between 1% and 6%. Forty-eight dermal responses were considered  
23 suggestive of sensitization or irritation with a mean rate of response of 0.26%. The authors  
24 concluded that sunscreen products formulated with 1% to 6% 2H4MBP do not possess a  
25 significant sensitization or irritation potential for the general public. 2H4MBP was also negative  
26 in an in vitro phototoxicity assay using SkinEthic™, a human epidermis model.<sup>50</sup>

#### 27 **Study Rationale**

28 2H4MBP was nominated to NTP by the National Cancer Institute because of high exposure via  
29 use of 2H4MBP-containing sunscreen products and lack of chronic toxicity and carcinogenicity  
30 data. 2H4MBP was also nominated by a private individual to ascertain genotoxic potential.  
31 Furthermore, there are concerns about the endocrine activity of 2H4MBP. Under the purview of  
32 the Sunscreen Innovation Act of 2014, FDA is in the process of reviewing toxicity data on  
33 specific commonly used sunscreens to ascertain whether the available data support a positive  
34 GRASE (generally recognized as safe and effective)<sup>51</sup> designation. FDA is also in the process of  
35 finalizing and making effective the Sunscreen Monograph, which will update conditions under  
36 which over-the-counter sunscreen products can be marketed in the United States. FDA had  
37 expressed concern about the potential long-term adverse effects,<sup>52</sup> or effects not otherwise  
38 readily detected from human use, and specifically identified reproductive toxicity and  
39 carcinogenicity as concerns. This concern was elevated due to data in the published literature  
40 suggesting potential for endocrine activity.

1 To understand the potential effects on reproduction and development, NTP conducted this study  
2 with continual 2H4MBP exposure in a sensitive animal model to address the potential for  
3 2H4MBP to (1) exhibit endocrine activity, (2) affect the ability of offspring to reproduce, and (3)  
4 induce adverse fetal effects. In addition, this study allowed for quantification of 2H4MBP in the  
5 blood at different ages for comparison to human blood concentrations. This report complements  
6 ICH<sup>b</sup> S5r2 guideline studies (fertility and early embryonic development, embryo-fetal  
7 development, and pre- and postnatal developmental studies in rats) on 2H4MBP<sup>53</sup> conducted by  
8 FDA's National Center for Toxicological Research, an interagency NTP partner, and allows for  
9 the comparison of study designs and outcomes. Potential endocrine activity that could result in  
10 neoplastic/tumorigenic responses was assessed in the concurrently conducted mouse and rat  
11 2-year toxicology and carcinogenesis studies. The 2-year rat study also included perinatal  
12 exposure.<sup>34</sup>

13 As disposition is similar following oral and dermal exposure, 2H4MBP exposure via the diet was  
14 selected for this study, rather than topical application, to sustain internal exposure. It was also  
15 recognized that if applied topically, internal dose would be influenced by intra- and inter-animal  
16 grooming behavior. To minimize the potential endocrine activity of phytoestrogens that are often  
17 present in rodent diets, a diet low in phytoestrogens was used. Ethinyl estradiol, a synthetic form  
18 of estrogen, was selected as a positive control to provide context for any potential estrogen-like  
19 findings in 2H4MBP-exposed rats, if present.

---

<sup>b</sup>ICH = International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use.

## 1 Materials and Methods

### 2 Overview of Pre- and Postnatal Dose Range-finding and Modified 3 One-Generation Study Designs

4 Modified one-generation (MOG) studies are composed of two interrelated parts: (1) a dose  
5 range-finding study (Figure 3) and (2) a MOG study (Figure 4, Table 1). If the acceptable range  
6 of exposure concentrations required to avoid excessive general and perinatal toxicity is  
7 unknown, a pre- and postnatal dose range-finding study is conducted. Nulliparous females are  
8 mated at the animal vendor and sent to the testing laboratory. Dosing typically begins at  
9 implantation (gestation day [GD] 6) through weaning on lactation day (LD) 28. Offspring are  
10 exposed in utero, during lactation, and through consumption of dosed feed.

11 In MOG studies, time-mated females are administered the test article from GD 6 through  
12 weaning (evidence of mating = GD 0). The subsequent F<sub>1</sub> litters are standardized to a specified  
13 litter size (n = 8 or 10), with equal representation of both sexes. These offspring are continuously  
14 exposed to the test article via the same route of exposure and dose concentration as their dams.  
15 Multiple endpoints indicative of potential endocrine alteration (e.g., anogenital distance [AGD],  
16 nipple retention in males, pubertal markers) are measured (Table 1). Randomly selected  
17 F<sub>1</sub> animals are taken to adulthood for gross and histopathological examinations and can be  
18 allocated at weaning (postnatal day [PND] 28) to various cohorts. Histopathological examination  
19 of multiple animals per litter increases the power of statistical tests to detect adverse effects.<sup>54</sup>

20

21 **Figure 3. Design of a Dose Range-finding Study**

22 F<sub>0</sub> dams are exposed to the test article from gestation day (GD) 6 through weaning on lactation day (LD) 28 and evaluated for  
23 maternal toxicity. F<sub>1</sub> offspring are exposed in utero through postnatal day (PND) 28 and evaluated for signs of in utero and  
24 postnatal toxicity.

1

2 **Figure 4. Design of a Modified One-Generation Rat Study**

3 Fo dams are exposed to the test article from gestation day (GD) 6 through weaning on lactation day (LD) 28 and evaluated for maternal toxicity. F1 offspring are exposed in utero  
 4 and during lactation through postnatal (PND) 28 and evaluated for signs of toxicity. After weaning, F1 offspring are allocated into cohorts for prenatal, reproductive performance,  
 5 or additional assessments (e.g., subchronic or biological sampling cohorts) and exposure to test article continues until necropsy. F2 offspring are exposed in utero and during  
 6 lactation and postweaning until necropsy (reproductive performance cohort).

1 The ability of F<sub>1</sub> animals to mate and produce viable offspring is evaluated in the reproductive  
 2 performance cohort. The potential for the test article to induce fetal defects is assessed in the  
 3 prenatal cohort: F<sub>2</sub> fetuses are examined on GD 21, which includes examination of external  
 4 morphology, fetal viscera, head (soft tissue and skeletal components), and skeleton (osseous and  
 5 cartilaginous defects). Abnormalities are categorized as either malformations, which are  
 6 permanent structural changes that could adversely affect survival, development, or function; or  
 7 variations, which are a divergence beyond the usual range of structural constitution that might  
 8 not adversely affect survival or health,<sup>55</sup> consistent with descriptions by Makris et al.<sup>56</sup> Endpoints  
 9 common to most cohorts are described in Table 1.

10 **Table 1. Key Modified One-Generation Study Design Endpoints**

Cohort	Key Endpoints
<b>F<sub>0</sub> Dams</b>	Maternal toxicity endpoints (body weight, feed consumption, clinical observations)
<b>F<sub>1</sub> Generation<sup>a</sup></b>	Clinical observations Body weights Feed consumption Necropsy Pup survival Anogenital distance, nipple/areola retention, testis descent, vaginal cytology
<b>Reproductive Performance Cohort</b>	F <sub>1</sub> reproductive performance F <sub>1</sub> andrology and sperm parameters F <sub>1</sub> histopathology F <sub>2</sub> litter size, viability, and growth F <sub>2</sub> necropsy
<b>Prenatal Cohort</b>	F <sub>1</sub> reproductive performance F <sub>2</sub> fetal external, visceral, skeletal, and head soft tissue examinations F <sub>2</sub> necropsy
<b>Subchronic Cohort</b>	F <sub>1</sub> hematology F <sub>1</sub> clinical chemistry F <sub>1</sub> histopathology

11 <sup>a</sup>Additional cohorts (e.g., biological sampling cohort) and associated endpoints may be included in the study design.

12 Subchronic toxicity, including effects on clinical chemistry and hematology, are assessed in a 3-  
 13 month cohort. Other cohorts can also be added (e.g., for internal dose estimation,  
 14 neurobehavioral, toxicokinetic, and/or immunotoxicity assessments) to identify potential hazards  
 15 across multiple functional outcomes. If necessary, more than one animal per sex can be selected  
 16 from each litter and assigned to a cohort (e.g., reproductive performance). The F<sub>1</sub> litter remains  
 17 the statistical unit but examining multiple animals per litter increases the likelihood of detecting  
 18 adverse responses and collectively makes the most use of the animals produced.

1 In the studies reported here, F<sub>0</sub> females were administered the test article in feed beginning on  
2 GD 6. F<sub>1</sub> and F<sub>2</sub> offspring were exposed in utero, during lactation, and through consumption of  
3 dosed feed.

## 4 **Procurement and Characterization**

### 5 **2-Hydroxy-4-methoxybenzophenone**

6 2-Hydroxy-4-methoxybenzophenone (2H4MBP) was obtained from Ivy Fine Chemicals (Cherry  
7 Hill, NJ) in a single lot (20100801), which was used in the dose range-finding and MOG studies.  
8 Identity and purity analyses were conducted under the analytical chemistry laboratory and study  
9 laboratory at Battelle (Columbus, OH) (Appendix A). Reports on analyses performed in support  
10 of the 2H4MBP studies are on file at the National Institute of Environmental Health Sciences  
11 (NIEHS).

12 Lot 20100801 of the chemical, a light-yellow powder, was identified as 2H4MBP by infrared  
13 (IR) and <sup>1</sup>H and <sup>13</sup>C nuclear magnetic resonance (NMR) spectroscopy. The IR spectrum was in  
14 good agreement with a reference spectrum (BP #824 from the Sadtler Basic Monomers and  
15 Polymers Library [Bio-Rad Laboratories, Hercules, CA]) and the structure of 2H4MBP. <sup>1</sup>H and  
16 <sup>13</sup>C NMR spectra were consistent with computer-predicted spectra and the structure of the test  
17 article.

18 The purity of 2H4MBP lot 20100801 was determined using high-performance liquid  
19 chromatography (HPLC) with ultraviolet (UV) detection, as well as gas chromatography (GC)  
20 with flame ionization detection (FID). Lot 20100801 was screened for common residual volatile  
21 solvents using GC with electron capture detection (ECD) and FID. Differential scanning  
22 calorimetry (DSC) was also used to determine the purity of 2H4MBP. Karl Fisher titration of  
23 2H4MBP lot 20100801 was conducted to estimate moisture content.

24 Purity assessment by HPLC/UV and GC/FID found one major peak with no reportable  
25 impurities ≥0.1%. Purity by DSC was 99.9%. Karl Fischer analysis indicated that no quantifiable  
26 water was present in 2H4MBP lot 20100801. No significant halogenated or nonhalogenated  
27 volatile impurities were found in the lot. The overall purity of 2H4MBP lot 20100801 was  
28 determined to be >99%.

29 To ensure stability, the bulk 2H4MBP was stored at room temperature (approximately 25°C) in  
30 sealed amber glass containers. Periodic analysis of the lot by the study laboratory using  
31 HPLC/UV showed no degradation of the bulk 2H4MBP chemical.

### 32 **Ethinyl Estradiol**

33 Ethinyl estradiol (EE) was obtained in a single lot (090M1241V) from Sigma-Aldrich (St. Louis,  
34 MO) via Government Scientific Source, Inc. (Reston, VA). Identity, purity, and stability analyses  
35 were conducted by the analytical chemistry laboratory at Battelle (Columbus, OH)  
36 (Appendix A).

37 EE lot 090M1241V was a white powder. The lot identity was confirmed using IR spectroscopy  
38 and <sup>1</sup>H and <sup>13</sup>C NMR spectroscopy; all spectra were consistent with the structure of EE and  
39 matched available reference and predicted spectra. Elemental analysis indicated that the sample

1 was approximately 80.4% carbon, 11.5% oxygen, 7.9% hydrogen, and >0.5% nitrogen, which is  
2 consistent with theoretical values.

3 HPLC/UV showed a major peak with 99.8% and one minor peak with 0.23% of the total peak  
4 area, and analysis for volatiles using headspace GC/FID found the sample contained  
5 approximately 0.023% acetone. DSC yielded a purity of 99.7% and a melting point of 184°C.  
6 Karl Fischer analysis indicated that the water content of lot 090M1241V was approximately  
7 0.4%. These data indicated the EE purity of lot 090M1241V to be  $\geq 99.7\%$ , consistent with the  
8 manufacturer-reported purity of 99%.

9 To ensure stability, the EE positive control was stored in sealed glass containers at room  
10 temperature. Prior to the study and at study termination, lot 090M1241V was analyzed using  
11 HPLC/UV to ensure chemical stability.

## 12 **Preparation and Analysis of Dose Formulations**

### 13 **2-Hydroxy-4-methoxybenzophenone**

14 Dosed feed formulations were prepared monthly (dose range-finding study) or eight times (MOG  
15 study) (Table A-2) using irradiated low-phytoestrogen feed (5K96 Casein diet). Formulations  
16 were stored at approximately 5°C for up to 42 days in amber glass bottles. The homogeneity of  
17 2H4MBP formulations in 5K96 feed was confirmed before conducting the studies. The  
18 analytical chemistry laboratory at Battelle (Columbus, OH) conducted all dose formulation  
19 analyses throughout the study.

20 Stability studies conducted on a 1,000 ppm formulation when sealed and stored in amber plastic  
21 bags for 42 days at 5°C or -20°C showed that the formulation was within 10% of the  
22 day 0 value. An animal room simulation of a 1,000 ppm formulation stored in open glass  
23 containers at room temperature, with and without rodent urine and feces, showed that 2H4MBP  
24 over 7 days was within 10% of the day 0 concentration. The preadministration dosed feed  
25 formulations were analyzed three times over the course of the study (Table A-3, Table A-4)  
26 using HPLC/UV. All preadministration samples were within 10% of the target concentration. For  
27 one set of dosed feed formulations, postadministration samples were collected from the animal  
28 room approximately 1 month after preparation. These formulations were also within 10% of the  
29 target concentrations.

### 30 **Ethinyl Estradiol**

31 Dosed feed formulations were prepared eight times (Table A-2) using 5K96 feed. Formulations  
32 were stored at -20°C for  $\leq 57$  days in sealed amber plastic bags. The homogeneity of 0.05 ppm  
33 EE formulations in 5K96 feed was confirmed before conducting the studies.

34 Stability studies conducted on the 0.05 ppm formulation, when stored in sealed amber plastic  
35 bags at -20°C, approximately 5°C, or room temperature for 57 days, showed that the formulation  
36 was within 10% of the day 0 value. An animal room simulation of the 0.05 ppm formulation in  
37 open glass containers, with and without rodent urine and feces, showed that EE over 8 days was  
38 within 10% of the day 0 value.

1 The preadministration dosed feed formulations were analyzed four times over the course of the  
2 study (Table A-4) using HPLC/UV. All preadministration samples were within 10% of the target  
3 concentration with the exception of two formulations, one of which was 11% below and the  
4 other 12% above. Postadministration samples were collected from the animal room at the end of  
5 the exposure period and sent to Battelle (Columbus, OH) for analysis. The concentrations of the  
6 animal room samples were within 10% of the preadministration analyses and, therefore,  
7 demonstrated acceptable stability during the study.

## 8 **Animal Source**

9 Female Sprague Dawley (Hsd:Sprague Dawley<sup>®</sup> SD<sup>®</sup>) rats were obtained from Envigo (formerly  
10 Harlan Laboratories, Inc., Dublin, VA) for use in the dose range-finding and MOG studies.  
11 Sexually mature (12 to 13 weeks old) females were time-mated overnight at the vendor and were  
12 received on GD 1 or GD 2 (13 to 14 weeks old) for both the dose range-finding and MOG  
13 studies. GD 0 was defined as the day positive evidence of mating was observed.

## 14 **Animal Health Surveillance**

15 In accordance with the National Toxicology Program (NTP) Sentinel Animal Program  
16 (Appendix C), 20 nonmated female rats were designated for disease monitoring after arrival;  
17 samples were collected for serological analyses, and the rats were euthanized, necropsied, and  
18 examined for the presence of disease or parasites. All test results were negative.

## 19 **Animal Welfare**

20 Animal care and use were in accordance with the Public Health Service Policy on Humane Care  
21 and Use of Laboratory Animals. All animal studies were conducted in a facility accredited by  
22 AAALAC International. Studies were approved by the RTI International Animal Care and Use  
23 Committee and conducted in accordance with all relevant National Institutes of Health and NTP  
24 animal care and use policies and applicable federal, state, and local regulations and guidelines.

## 25 **Experimental Design**

### 26 **Dose Range-finding Study**

27 Time-mated female rats were received on GD 1 or GD 2, randomized based on GD 3 body  
28 weight, and placed on a 5K96 Casein diet containing 0, 3,000, 10,000, 25,000, or 50,000 ppm  
29 2H4MBP from GD 6 through LD 28. Feed and water were available ad libitum; information on  
30 feed composition and contaminants is provided in Appendix B. Dose selection was based in part  
31 on Fischer 344/N rat studies reported in Toxicity Report 21.<sup>40</sup>

32 Eight time-mated rats were allocated to each exposure group. Six additional time-mated female  
33 rats were allocated to the control, 3,000, and 50,000 ppm groups for collection of tissues for  
34 bioanalytical method development. Viability, clinical observations, body weights, pup counts  
35 (litters were not standardized), and feed consumption were recorded to help determine the  
36 maximum exposure concentration that could be tolerated by the dams while not affecting the  
37 number of pups, so the MOG study could be populated with a sufficient number of offspring.  
38 Maternal plasma, amniotic fluid, and fetuses were collected from three separately allocated dams  
39 on GD 18. On LD 4 and PND 4, maternal plasma and pups (three per sex), respectively, were

1 collected from two to three dams per group. On LD 28, a piece of the left lateral lobe of the liver,  
2 left and right kidneys, left and right ovaries, and uterus were collected from five dams per group.  
3 In addition, left and right testes, left and right epididymides, and the brain were collected from  
4 10 male pups per group on PND 28. All other dams and pups were euthanized without further  
5 examination on LD 28 and PND 28, respectively. Females that did not litter were euthanized  
6 approximately 5 days after expected littering, received a gross necropsy, and had their pregnancy  
7 status determined. If present, the numbers of implantation sites were recorded. F<sub>1</sub> pups that were  
8 removed for health reasons or morbidity received a gross necropsy. Further details of animal  
9 maintenance and study design are given in Table 2.

## 10 **Modified One-Generation Study with Prenatal and Reproductive** 11 **Performance Cohorts**

12 Time-mated F<sub>0</sub> female rats, 25 per group, were received on GDs 1 or 2, randomized based on  
13 GD 3 body weight, and placed on a 5K96 Casein diet containing 0, 3,000, 10,000, or 30,000 ppm  
14 2H4MBP or 0.05 ppm EE ad libitum on GD 6. The exposure concentration of 30,000 ppm was  
15 expected to result in minimal maternal toxicity and to ensure that the model system was  
16 appropriately challenged, increasing the likelihood of identifying any toxicological signal in the  
17 offspring. The F<sub>1</sub> and F<sub>2</sub> generations were exposed to 2H4MBP or EE via the mother during  
18 gestation and lactation, and directly via 5K96 feed at the same exposure concentration as their  
19 respective dams. Viability, clinical observations, body weights, pup counts, and feed  
20 consumption were recorded. F<sub>1</sub> and F<sub>2</sub> litters were standardized to 8 pups (4/sex/litter, when  
21 possible) on PND 4. At weaning on PND 28, offspring were randomly assigned to reproductive  
22 performance (2/sex/litter), prenatal development (1/sex/litter), or biological sample collection  
23 (1/sex/litter) cohorts. Information on feed composition and contaminants is provided in  
24 Appendix B. Additional details of animal maintenance and study design are given in Table 2 and  
25 Table 3.

## 26 **Endocrine-sensitive and Pubertal Endpoints**

27 AGD and corresponding body weight (for covariate analyses) were recorded for each F<sub>1</sub> and  
28 F<sub>2</sub> pup on PND 1. AGD was measured using a stereomicroscope with a calibrated ocular reticle.  
29 The distance between the midpoint of the anal opening to the caudal edge of the genital papilla  
30 was recorded and converted to millimeters (mm). F<sub>1</sub> and F<sub>2</sub> male pups were evaluated for  
31 retention of areolae/nipples on PND 13 and observed for testicular descent over 25 (F<sub>1</sub>) or  
32 28 (F<sub>2</sub>) days beginning on PND 14. Acquisition of balanopreputial separation (BPS), defined as  
33 complete retraction of the prepuce from the glans penis, was evaluated in all F<sub>1</sub> males over  
34 59 days beginning on PND 35, and body weight was recorded upon BPS acquisition. External  
35 genitalia were examined for malformations and undescended testes (cryptorchidism). The  
36 acquisition of vaginal opening (VO) was evaluated in F<sub>1</sub> females over 48 days beginning on  
37 PND 23, and the corresponding body weight recorded upon VO acquisition.

## 38 **Vaginal Cytology**

39 Beginning on PND 75, vaginal lavages were collected from the F<sub>1</sub> females in the prenatal and  
40 reproductive performance cohorts for 16 consecutive days for evaluation of estrous cyclicity and  
41 confirmation of mating. Vaginal vaults were moistened with saline, if necessary, and samples of  
42 vaginal fluid and cells were spotted onto a slide and stained with toluidine blue. Relative  
43 numbers of leukocytes, nucleated epithelial cells, and large squamous epithelial cells were

1 determined and used to ascertain estrous cycle stages (diestrus, proestrus, estrus, and  
2 metestrus).<sup>57</sup>

### 3 **F<sub>1</sub> Cohabitation and Assessment of Mating**

4 Sexually mature F<sub>1</sub> animals in the prenatal (14–15 weeks; 1 male and 1 female/litter) and  
5 reproductive performance (17–18 weeks; 2 males and 2 females/litter) cohorts were randomly  
6 assigned a mating partner, avoiding sibling pairings, and paired in a 1:1 ratio for up to 15 days.  
7 Mating was confirmed by daily examination for the presence of a vaginal copulation plug or  
8 sperm in a vaginal lavage. The day of confirmed mating was considered GD 0. Females that did  
9 not exhibit evidence of mating or did not deliver a litter were necropsied 25 days after the  
10 cohabitation period ended. The uterus was examined grossly and stained with ammonium sulfide  
11 to identify potential implantation sites. The number of corpora lutea on the ovary were  
12 enumerated, and gross lesions were examined for histopathological changes.

### 13 **Prenatal Cohort**

14 On GD 21, fetuses were removed from the uterus, individually weighed (live fetuses only), and  
15 examined externally for alterations, including inspection of the oral cavity for cleft palate.  
16 Placental morphology was also evaluated. Live fetuses were subsequently euthanized by oral  
17 administration of sodium pentobarbital. Females with no evidence of mating were necropsied  
18 and examined for gross lesions, which were retained and examined histologically. Fetal sex was  
19 confirmed by inspection of gonads in situ. All fetuses were examined for soft tissue alterations  
20 under a stereomicroscope.<sup>58; 59</sup> The heads were removed from approximately half of the fetuses  
21 in each litter, fixed in Bouin's solution, and subsequently examined by freehand sectioning.<sup>60</sup>  
22 This technique precludes skeletal evaluations of the skull; therefore, remaining heads and all  
23 fetuses were eviscerated, fixed in ethanol, macerated in potassium hydroxide, stained with  
24 Alcian blue and Alizarin red, and examined for subsequent cartilage and osseous alterations.<sup>61; 62</sup>  
25 External, visceral, and skeletal fetal findings were recorded as developmental variations or  
26 malformations. After positive evidence of mating, male sires were necropsied, selected organs  
27 were weighed, and gross lesions were collected for potential histological examination.

### 28 **Reproductive Performance Cohort**

29 Fertility and fecundity were assessed in two males and two females from each F<sub>1</sub> litter and all  
30 exposure groups. Pup viability was assessed daily during lactation. F<sub>2</sub> offspring were  
31 standardized to a litter size of 8 pups (4/sex/litter, when possible) on PND 4. F<sub>1</sub> males were  
32 euthanized at approximately 22 weeks of age after assessment of fertility, fecundity, and  
33 F<sub>2</sub> generation pup survival. The F<sub>1</sub> females and the F<sub>2</sub> offspring were euthanized on PND 28,  
34 when the F<sub>1</sub> females were 18–24 weeks of age. F<sub>2</sub> offspring were given a gross necropsy. F<sub>1</sub> sires  
35 were necropsied after mating, selected organs were weighed, and gross lesions were collected for  
36 potential histological examination. Given the absence of functional changes, a crossover mating  
37 to determine affected sex was deemed unnecessary.

38 Immediately after euthanasia, the left testis and epididymis were removed, trimmed, and  
39 weighed. The cauda epididymis was then weighed, and samples were collected for determining  
40 cauda epididymal sperm motility, number, and density via automated sperm analyzer (Hamilton  
41 Thorne, Inc., Beverly, MA). The sampled left cauda epididymis and the intact corpus and caput  
42 were frozen at –80°C for subsequent determination of epididymal sperm concentration from the  
43 left cauda epididymis. The left testis was frozen at –80°C for subsequent determination of

1 homogenization-resistant spermatid head counts for calculations of daily sperm production and  
2 efficiency of daily sperm production.<sup>63</sup> The right testis and epididymis were examined  
3 histologically. Gross lesions took precedence over sperm parameter assessments (i.e., if the left  
4 testis was grossly abnormal, it and the left epididymis would be examined histologically, and the  
5 right testis and epididymis, if grossly normal, would be subjected to sperm assessments).

### 6 **Biological Sampling Cohort**

7 On PND 28 and PND 56 (5/sex/time point/exposure group), kidneys, epididymides, testes,  
8 ovaries, and liver were collected and frozen for potential future analyses. Plasma samples were  
9 also collected from these rats on PNDs 28 and 56 (5/sex/time point/exposure group) and  
10 analyzed for 2H4MBP and metabolites.<sup>64</sup>

### 11 **Necropsy and Histopathology**

12 Complete necropsies were performed on adult F<sub>1</sub> males and F<sub>1</sub> females in the reproductive  
13 performance cohort; unscheduled deaths, F<sub>0</sub> females, F<sub>1</sub> males, and F<sub>1</sub> females in the prenatal  
14 cohort; F<sub>1</sub> females in the reproductive performance cohort that either had no evidence of mating  
15 or did not produce a litter; and F<sub>2</sub> offspring. All gross lesions were examined histologically. In  
16 addition, several protocol-required tissues were examined microscopically from the adult  
17 F<sub>1</sub> males and females in the reproductive performance cohorts.

18 The initial histological examination was performed by an experienced, board-certified veterinary  
19 pathologist. The slides, individual animal data records, and pathology tables were subsequently  
20 evaluated by an independent quality assessment (QA) laboratory. The individual animal records  
21 and tables were compared for accuracy, the slide and tissue counts were verified, and the  
22 histotechnique was evaluated. A QA pathologist evaluated selected slides from the various  
23 cohorts. Kidney histopathology was reviewed from all males and females in the F<sub>1</sub> reproductive  
24 performance cohort and from animals in other cohorts in which the kidney had gross lesions. The  
25 urinary bladder, thyroid gland, liver, testis, epididymis, and ovaries were reviewed from all  
26 animals in the F<sub>1</sub> reproductive performance cohort for which the tissue had been previously  
27 examined by the study laboratory pathologist.

28 The QA report and the reviewed slides were submitted to the NTP pathologist, who reviewed  
29 and addressed any inconsistencies in the diagnoses made by the laboratory and QA pathologist.  
30 The QA pathologist, who served as the coordinator of the Pathology Working Group (PWG),  
31 presented representative histopathology slides containing examples of lesions related to test  
32 article administration, examples of disagreements in diagnoses between the laboratory and QA  
33 pathologist, or lesions of general interest to the PWG for review. The PWG consisted of the NTP  
34 pathologist and other pathologists experienced in rodent toxicological pathology. When the PWG  
35 consensus differed from the opinion of the laboratory pathologist, the diagnosis was changed.  
36 Final diagnoses for reviewed lesions represent a consensus between the laboratory pathologist,  
37 QA pathologist, and the PWG. Details of these review procedures have been described, in part,  
38 by Maronpot and Boorman<sup>65</sup> and Boorman et al.<sup>66</sup>

1 **Table 2. Experimental Design and Materials and Methods in the Dose Range-finding and Modified**  
 2 **One-Generation Studies of 2-Hydroxy-4-methoxybenzophenone (Prewaning)**

Dose Range-finding Study	Modified One-Generation Study
<b>Study Laboratory</b>	
RTI International (Research Triangle Park, NC)	Same as dose range-finding study

<b>Type and Frequency of Observation of F<sub>0</sub> and F<sub>1</sub> Dams</b>	
Viability was assessed at least twice daily, and clinical observations were recorded at least once daily. Female body weights were recorded daily during gestation (GD 3–21) and during lactation on LDs 1, 4, 7, 14, 21, 25, and 28. Feed consumption was recorded at 3-day intervals from GD 3 through GD 21 and for LDs 1–4, 4–7, 7–14, 14–21, 21–25, and 25–28.	Viability was assessed at least twice daily, and clinical observations were recorded at least once daily. Female body weights were recorded daily during gestation (GD 3–21) and during lactation on LDs 1, 4, 7, 10, 13, 16, 19, 21, 25, and 28. Feed consumption was recorded at 3-day intervals from GD 3 through GD 21 and LD 1 through LD 28.

Dose Range-finding Study	Modified One-Generation Study
<p><b>Type and Frequency of Observation of F<sub>1</sub> and F<sub>2</sub> Pups</b></p>	
<p>Viability was assessed at least twice daily, and clinical observations were recorded at least once daily. The number of live and dead pups in each litter was counted daily. Individual pups were sexed and weighed on PNDs 1, 4, 7, 14, 21, 25, and 28. Litters were not standardized on PND 4, and all offspring (unless euthanized and biological samples collected for subsequent analytical method development) were retained until PND 28 to assess litter size, sex distribution, pup body weights, and survival during lactation.</p>	<p>Viability was assessed at least twice daily, and clinical observations were recorded at least once daily. The number of live and dead pups in each litter was counted daily. Individual pups were sexed and weighed on PNDs 1, 4, 7, 10, 13, 16, 19, 21, 25, and 28. Litters were standardized to a litter size of 8 pups (4/sex/litter, when possible) on PND 4.</p> <p>Endocrine F<sub>1</sub>/F<sub>2</sub> endpoints: AGD and corresponding pup weight on PND 1; areolae/nipple retention on PND 13; testicular descent beginning on PND 14</p>
<p><b>Primary Method of Euthanasia</b></p>	
<p>100% carbon dioxide (F<sub>0</sub> females and PND 28 pups); intraperitoneal injection of a solution containing sodium pentobarbital or decapitation (GD 21 fetuses; PND 4 pups)</p>	<p>100% carbon dioxide (adults and PND 28 pups) or administration of a solution containing sodium pentobarbital (PND 4 pups [intraperitoneal injection]; GD 21 fetuses [oral])</p>
<p><b>Necropsy and Postmortem Evaluation</b></p>	
<p>F<sub>0</sub> dams were euthanized on LD 28 without necropsy. Females that did not litter were euthanized ~5 days after expected littering, received a gross necropsy, and had their pregnancy status determined. If present, the numbers of implantation sites and corpora lutea were recorded. F<sub>1</sub> pups that were removed for health reasons or died received a gross necropsy.</p>	<p>F<sub>0</sub> dams were euthanized on LD 28, received a gross necropsy, and had their number of implantation sites recorded. Females that did not litter were euthanized 3 days after expected littering, received a gross necropsy, and had their pregnancy status determined. If present, the number of implantation sites and corpora lutea were recorded. Histopathological analysis of gross lesions was performed if collected.</p>
<p><b>Internal Dose Assessment/Additional Tissue Collection</b></p>	
<p>On GD 18, maternal plasma, amniotic fluid, and fetuses were collected from 3 pregnant dams/exposure group from the 0, 3,000, and 50,000 ppm groups. On LD 4, maternal plasma was collected from 2 or 3 dams/exposure group from the 0, 3,000, and 50,000 ppm groups. On PND 4, pups (3/sex) were collected from 2 or 3 dams/exposure group from the 0, 3,000, and 50,000 ppm groups. On LD 28, a piece of the left lateral lobe of the liver, left and right kidneys, left and right ovaries, and uterus were collected from 5 dams/exposure group. In addition, left and right testes, left and right epididymides, and the brain were collected from 10 male pups/exposure group on PND 28. Sample collection preceded the analytical method protocol development and method validation. Following the analysis and evaluation of a sample subset, the analysis of the full sample set was not pursued due to potential instability of analytes during long-term storage.</p>	<p>On PNDs 28 and 56 (5/sex/time point/exposure group), kidneys, epididymides, testes, ovaries, and liver were collected from rats in the biological sampling cohort and frozen for potential future analyses. Plasma samples were also collected from these rats on PNDs 28 and 56 (5/sex/time point/exposure group) and analyzed for 2H4MBP and metabolites.<sup>64</sup></p>

1 GD = gestation day; LD = lactation day; PND = postnatal day; 2H4MBP = 2-hydroxy-4-methoxybenzophenone; EE = ethinyl  
2 estradiol; AGD = anogenital distance.

1 **Table 3. Experimental Design and Materials and Methods in the Modified One-Generation Study**  
 2 **of 2-Hydroxy-4-methoxybenzophenone (Postweaning)**

<b>Modified One-Generation Study</b>	
<b>F<sub>1</sub> Postweaning Assessments</b>	
<p><b>All Cohorts:</b> Viability was assessed at least twice daily, and clinical observations recorded at least once daily. F<sub>1</sub> male body weights and feed consumption were recorded once weekly. F<sub>1</sub> female body weights and feed consumption were recorded at least once weekly during the pre mating interval. Vaginal opening (and concomitant body weight) was evaluated beginning on PND 23, balanopreputial separation (and concomitant body weight) was evaluated beginning on PND 35.</p> <p><b>Prenatal and Reproductive Performance Cohorts:</b> After collection of vaginal lavage samples for 16 days, F<sub>1</sub> nonsibling mating pairs (1 male and 1 female/litter or 2 males and 2 females/litter) from the same exposure group were cohabitated until evidence of mating or for ≤15 days. F<sub>1</sub> dams were observed for the same gestational endpoints as the F<sub>0</sub> dams.</p> <p><b>Reproductive Performance Cohort:</b> F<sub>1</sub> dams and F<sub>2</sub> pups were evaluated for the same lactational endpoints as the F<sub>0</sub> dams and F<sub>1</sub> pups. A crossover mating would have been considered if an effect on fertility was observed.</p>	
<b>F<sub>1</sub> Necropsy and Postmortem Evaluation</b>	
<p><b>Prenatal Cohort:</b> F<sub>1</sub> dams were euthanized on GD 21. Necropsies were performed on all females. Terminal body weights and adrenal glands (paired), liver, ovaries (left and right), and gravid uterus weights were recorded. The number of corpora lutea on each ovary was recorded. The number and location of all fetuses and resorptions (early or late) and the total number of implantation sites were recorded. If there were no macroscopic evidence of pregnancy, the uterus was stained to visualize potential evidence of implantation sites. Live fetuses were counted, sexed, weighed, and examined for external morphological abnormalities, including examination of the oral cavity for cleft palate. Placental morphology was also evaluated. Live fetuses were euthanized and then examined for visceral morphological abnormalities by fresh dissection. The sex of each fetus was confirmed by internal examination. The heads from approximately one-half of the fetuses in each litter were fixed, sectioned, and examined. All fetuses were eviscerated, fixed, stained, and examined for skeletal developmental variations, malformations, or other morphological findings. After positive evidence of mating, male sires were weighed, euthanized, and necropsied, and the following organ weights recorded: adrenal glands (paired), testes (left and right), epididymides (left and right), kidneys, liver, dorsolateral and ventral prostate gland, seminal vesicles with coagulating glands, thyroid gland (fixed), LABC muscle, Cowper's glands (paired), and preputial glands. Histopathology of gross lesions was assessed.</p> <p><b>Reproductive Performance Cohort:</b> F<sub>1</sub> dams were euthanized on LD 28, and sires were euthanized within approximately 1 week of their mating partner. Terminal body weights and the following organ weights were recorded: adrenal glands (paired), liver, kidneys (left and right), ovaries (left and right), uterus, cervix, vagina, testes (left and right), epididymides (left and right), cauda epididymis, dorsolateral and ventral prostate gland, seminal vesicles with coagulating glands, thyroid gland (fixed), LABC muscle, Cowper's glands (paired), and preputial glands. Histopathology was performed on the following organs (predominantly reproductive tissues): adrenal glands, liver, kidneys, pituitary gland, thyroid gland, ovaries, testes, epididymides, dorsolateral and ventral prostate gland, seminal vesicles, coagulating glands, LABC muscle, Cowper's glands, preputial glands, and gross lesions. Cauda epididymal sperm motility, cauda epididymal sperm concentration, and testicular sperm head counts were also assessed.</p> <p><b>Biological Sampling Cohort:</b> At weaning, F<sub>1</sub> rats were randomly allocated for collection of biological samples. Rats were subjected to a gross necropsy, and the following tissues were collected on PNDs 28 and 56 (5/sex/time point/exposure group): plasma, kidneys, epididymides, testes, ovaries, and liver. Tissues were frozen at -70°C until analysis. Results of the plasma analyses had been reported previously.<sup>64</sup></p>	
3	PND = postnatal day; GD = gestation day; LABC = levator ani/bulbocavernosus; LD = lactation day..

## 1 **Statistical Methods**

2 Statistical methods were chosen based on distributional assumptions as well as on the need to  
3 incorporate within-litter correlation among animals. Unless specifically mentioned, all endpoints  
4 were tested for a trend across exposure groups, followed by pairwise tests for each exposed  
5 group against the negative control group. Significance of all trend and pairwise tests is reported  
6 at both 0.05 and 0.01 levels.

7 In the main study, the positive control (EE) was analyzed only by a single pairwise comparison  
8 to the negative control. The positive control analysis was kept separate from that of the other  
9 exposed groups and was excluded from all trend tests.

## 10 **Analysis of Fetal Malformations and Variations**

11 Incidences of malformations and variations in the fetuses were summarized as number of litters  
12 affected and as number of fetuses affected. Trend and pairwise analyses of the fetal  
13 malformations and variations was conducted using a Cochran-Armitage test with a Rao-Scott  
14 adjustment, as described below.

15 The tendency of fetuses from the same litter to respond more similarly than fetuses from  
16 different litters has been referred to as the “litter effect”<sup>67</sup> and reflects littermates’ similarities in  
17 genetics and in utero experiences. Failure to account for correlation within litters leads to  
18 underestimates of variance in statistical tests, resulting in higher probabilities of Type I errors  
19 (“false positives”). Therefore, the Cochran-Armitage test was modified to accommodate litter  
20 effects using the Rao-Scott approach.<sup>68</sup> The Rao-Scott approach accounts for litter effects by  
21 estimating the ratio of the variance in the presence of litter effects to the variance in the absence  
22 of litter effects. This ratio is then used to adjust the sample size downward to yield the estimated  
23 variance in the presence of litter effects. The Rao-Scott approach was implemented in the  
24 Cochran-Armitage test as recommended by Fung et al.,<sup>69</sup> formula  $\bar{T}_{RS2}$ .

## 25 **Analysis of Incidences of Gross Pathology and Morphology Findings**

26 For the F<sub>0</sub> dams, incidences of gross findings and histopathology were summarized as number of  
27 animals affected. Because some of these animals did not survive until the removal day for their  
28 cohort, analysis of the histopathological findings was conducted using the Poly-3 test, as  
29 described below.

30 The Poly-k test<sup>70-72</sup> was used to assess neoplasm and nonneoplastic lesion prevalence. This test is  
31 a survival-adjusted quantal-response procedure that modifies the Cochran-Armitage trend test to  
32 account for survival differences. Following Bailer and Portier,<sup>70</sup> a value of  $k = 3$  was used in the  
33 analysis of site-specific lesions. Variation introduced by the use of risk weights, which reflect  
34 differential mortality, was accommodated by adjusting the variance of the Poly-3 statistic as  
35 recommended by Bieler and Williams.<sup>73</sup> Poly-3 tests used the continuity correction described by  
36 Nam.<sup>74</sup>

37 For the F<sub>1</sub> and F<sub>2</sub> animals, incidences of gross findings and histopathology were summarized as  
38 number of litters affected and number of animals affected. To account for within-litter  
39 correlation, the Rao-Scott adjustment (as described earlier) was applied to the Cochran-Armitage

1 test in the analysis of this data. For histopathological data in F<sub>1</sub> cohorts in which survival issues  
2 could apply, the Poly-3 correction was also applied.

3 All p values calculated for gross pathological and histopathological data are one-sided and  
4 include a continuity correction.

## 5 **Analysis of Continuous Endpoints**

6 Before statistical analysis, extreme values identified by the outlier test of Dixon and Massey<sup>75</sup> for  
7 small samples ( $n < 20$ ) and Tukey's outer fences method<sup>76</sup> for large samples ( $n \geq 20$ ) were  
8 examined by NTP personnel, and implausible values were eliminated from the analysis.

9 In some instances, no considerations for litter effects were necessary in the analysis of the  
10 continuous data. This was the case for the F<sub>0</sub> generation and for the F<sub>1</sub> prenatal cohort for which  
11 there was only one animal per litter. In these instances, organ and body weight measurements,  
12 which historically have approximately normal distributions, were analyzed with the parametric  
13 multiple comparison procedures of Dunnett<sup>77</sup> and Williams.<sup>78; 79</sup>

14 When litter effects were present, organ and body weight endpoints were analyzed using linear  
15 mixed models, with litters as a random effect. To adjust for multiple comparisons, a Dunnett-Hsu  
16 adjustment was used.<sup>80</sup> Pup and fetal weights were adjusted for litter size by covariate analysis  
17 (see below) before analysis. AGD was adjusted for the body weight of the pup taken on the day  
18 of AGD measurement. The adjusted AGDs were analyzed as normal variates with litter effects  
19 using a linear mixed model.

20 Feed consumption, litter sizes, pup survival, implantations, number of resorptions, uterine  
21 content endpoints, spermatid, and epididymal spermatozoal measurements typically have skewed  
22 distributions. When litter effects were not present, these endpoints were analyzed using the  
23 nonparametric multiple comparison methods of Shirley<sup>81</sup> (as modified by Williams<sup>82</sup> and  
24 Dunn<sup>83</sup>). For these endpoints, the Jonckheere test<sup>84</sup> was used to assess the significance of the  
25 exposure concentration-related trends and to determine, at the 0.01 level of significance, whether  
26 a trend-sensitive test (the Williams or Shirley test) was more appropriate for pairwise  
27 comparisons than a test that does not assume a monotonic exposure concentration-related trend  
28 (the Dunnett or Dunn test).

29 When litter effects were present for non-normally distributed continuous endpoints, the trend  
30 across exposure groups was analyzed by a permutation test based on the Jonckheere trend test  
31 implemented by randomly permuting whole litters across exposure groups and bootstrapping  
32 within the litters (see, for example, Davison and Hinckley<sup>85</sup>). Pairwise comparisons were made  
33 using a modified Wilcoxon test that incorporated litter effects.<sup>86</sup> The Hommel procedure was  
34 used to adjust for multiple comparisons.<sup>87</sup>

## 35 **Analysis of Gestational and Fertility Indices**

36 When litter effects were not present, Cochran-Armitage trend tests were used to test the  
37 significance of trends in gestational and fertility indices across exposure groups. Fisher's exact  
38 test was used to conduct pairwise comparisons of each exposed group with the control group.  
39 P values for these analyses are two-sided.

1 When litter effects were present, as with the F<sub>1</sub> reproductive performance cohort, the gestational  
2 and fertility indices were tested using the Rao-Scott adjustment to the Cochran-Armitage test.  
3 This practice was used for both the trend and pairwise tests.

#### 4 **Body Weight Adjustments**

5 Because body weights typically decrease with increasing litter size, adjusting body weight for  
6 litter size in the analysis of fetal and pup weights can provide additional precision to detect test  
7 article effects.<sup>88</sup> Body weight adjustments are appropriate when the litter effect, as evidenced by  
8 decreasing weights with increasing litter size, is relatively constant across exposure  
9 concentrations. Adjusted fetal weights were calculated by fitting a linear model to littermean  
10 fetal weights as a function of litter size and exposure concentration, and the estimated coefficient  
11 of litter size was then used to adjust each litter mean fetal weight based on the difference  
12 between its litter size and the mean litter size. Prewaning pup body weights were adjusted for  
13 live litter size as follows. A linear model was fit to body weights as a function of exposure  
14 concentration and litter size. The estimated coefficient of litter size was then used to adjust each  
15 pup body weight based on the difference between its litter size and the mean litter size.  
16 Prestandardization PND 4 body weights were adjusted for PND 1 litter size, and body weights  
17 measured between PND 4 poststandardization and PND 21 were adjusted for PND 4  
18 poststandardization litter size. After adjustment, mean body weights were analyzed with a linear  
19 mixed model with a random litter effect.

#### 20 **Analysis of Time-to-Event Data**

21 Time-to-event endpoints, such as day of attainment of testicular descent, BPS, and VO, have four  
22 features that require careful model selection: (1) they might display non-normality; (2) litter-  
23 based correlation might be present; (3) values might be censored, meaning attainment is not  
24 observed before the end of the observation period; and (4) growth retardation, reflected in the  
25 weaning weight, is an important covariate in the case of BPS and VO given the relationship  
26 between normal day of expected attainment and body weight.

27 For this study, attainment times were approximately normally distributed and attainment was  
28 observed in all but three animals (from the same litter, BPS only). Under these circumstances, a  
29 mixed model approach is appropriate. The mixed model used here was fit to attainment day as a  
30 function of exposure concentration, as well as a function of both exposure concentration and  
31 weaning weight (for BPS and VO) with a random litter effect.

32 To calculate mean attainment values adjusted for weaning weight, a linear model was fit to  
33 attainment day as a function of exposure concentration and weaning weight. The estimated  
34 coefficient of weaning weight was then used to adjust each attainment day based on the  
35 difference between the measured weaning weight and the mean weaning weight.

36 Cumulative response percentage, obtained using the methods of Kaplan-Meier,<sup>89</sup> was plotted  
37 against time to attainment for unadjusted attainment times as well as attainment times adjusted  
38 for weaning weight. For litter-based plots, the litter median was used as time to attainment if  
39 >50% of the pups for that litter attained. Otherwise, litters with ≤50% of the pups attaining had  
40 time to attainment set to the final day of observation. These litters are included in the  
41 denominator of Kaplan-Meier calculations but not the numerator.

## 1 **Analysis of Vaginal Cytology Data**

2 Vaginal cytology data consist of daily observations of estrous cycle stages over a 16-day period.  
3 Differences from the control group for cycle length and number of cycles were analyzed using a  
4 Datta-Satten modified Wilcoxon test with a Hommel adjustment for multiple comparisons.

5 To identify disruptions in estrous cyclicity, a continuous-time Markov chain model (multi-state  
6 model) was fit using a maximum likelihood approach,<sup>90</sup> producing estimates of stage lengths for  
7 each exposure concentration group. Confidence intervals for these estimates were obtained based  
8 on bootstrap sampling of the individual animal cycle sequences. Stage lengths that were  
9 significantly different than the control group were identified using permutation testing with a  
10 Hommel adjustment.

## 11 **Historical Control Data**

12 The concurrent control group is the most valid comparison to the exposed groups and is the only  
13 control group analyzed statistically in NTP developmental and reproductive toxicity studies.  
14 However, historical control data are often helpful in interpreting potential exposure  
15 concentration-related effects, particularly for uncommon fetal findings that occur at a very low  
16 incidence. For meaningful comparisons, the conditions for studies in the historical control  
17 database must be generally similar. Factors that might affect the background incidences of fetal  
18 findings at a variety of sites are diet, strain/stock, route of exposure, study type, and/or laboratory  
19 that conducted the study. The NTP historical control database for fetal findings contains all fetal  
20 evaluations from teratology studies and/or modified one-generation studies for each laboratory.  
21 In general, the historical control database for a given study includes studies using the same route  
22 of administration and study design. However, historical control data for rats in this NTP  
23 Developmental and Reproductive Toxicity Technical Report contain data from feed and gavage  
24 (all routes) studies conducted at RTI International. The concurrent controls are included in the  
25 historical control data set. NTP historical controls are available online at  
26 <https://ntp.niehs.nih.gov/data/controls/index.html>.

## 27 **Quality Assurance Methods**

28 This study was conducted in compliance with Food and Drug Administration Good Laboratory  
29 Practice Regulations, Title 21 of the United States Code of Federal Regulations Part 58.<sup>91</sup> In  
30 addition, this study was audited retrospectively by an independent QA contractor. Separate audits  
31 covered completeness and accuracy of the pathology data, pathology specimens, final pathology  
32 tables, and a draft of this NTP Developmental and Reproductive Toxicity Report. Audit  
33 procedures and findings are presented in the reports and are on file at NIEHS. The audit findings  
34 were reviewed and assessed by NTP staff, and all comments were resolved or otherwise  
35 addressed during the preparation of this report.

## 2 Data Availability

3 The National Toxicology Program (NTP) evaluated all study data. Data relevant for evaluating  
4 toxicological findings are presented here. All study data are available in the NTP Chemical  
5 Effects in Biological Systems (CEBS) database: [https://doi.org/10.22427/NTP-DATA-DART-](https://doi.org/10.22427/NTP-DATA-DART-05)  
6 [05](https://doi.org/10.22427/NTP-DATA-DART-05).<sup>92</sup>

## 7 Dose Range-finding Study

### 8 Maternal Findings

#### 9 Viability and Clinical Observations

10 One F<sub>0</sub> rat in the 3,000 ppm group was euthanized on study day 5 before the start of dosed feed  
11 administration due to the presence of excessive red eye discharge (too early to determine  
12 pregnancy status) (Appendix E). No clinical observations were attributed to  
13 2-hydroxy-4-methoxybenzophenone (2H4MBP) exposure in any group during gestation or  
14 lactation (Appendix E).

#### 15 Body Weights and Feed Consumption

16 F<sub>0</sub> females exposed to 50,000 ppm 2H4MBP displayed lower body weights than the control  
17 group (Table 4; Figure 5). The mean body weight of dams in the 50,000 ppm group on gestation  
18 day (GD) 21 was significantly decreased by 11% compared to the control group, and the mean  
19 body weight gain of dams in the 50,000 ppm group over gestation (GD 6–21) was significantly  
20 decreased by 35%. This difference was attributed to a transient body weight loss over the GD 6–  
21 9 interval and lower body weight gains over most of the subsequent intervals and not attributed  
22 to smaller litters or lower fetal weights (Appendix E). F<sub>0</sub> females exposed to 10,000 or  
23 25,000 ppm 2H4MBP displayed similar 20% significant decreases in body weight gain over the  
24 GD 6–21 interval, which were attributed to lower body weights during the early gestation period  
25 (Table 4).

26 Lactation mean body weights were significantly decreased in dams exposed to 50,000 ppm  
27 2H4MBP relative to the control group (Table 4; Figure 5). This decrease was similar in  
28 magnitude to that observed at the end of gestation and likely related to the significantly  
29 decreased body weights observed during gestation.

30 In general, feed consumption during gestation in the 2H4MBP-exposed groups was higher than  
31 in the control group (Table 5). Feed consumption was significantly increased at several time  
32 intervals in the 25,000 and 50,000 ppm groups, and likely signifies poor palatability and  
33 subsequent feed wastage given the high concentration of 2H4MBP in the feed. 2H4MBP intake  
34 for F<sub>0</sub> females in the 3,000, 10,000, 25,000, and 50,000 ppm 2H4MBP groups, based on  
35 measured feed consumption and dietary concentrations for GD 6–21 interval, was approximately  
36 215, 695, 2,086, and 6,426 mg 2H4MBP/kg body weight/day (mg/kg/day), respectively  
37 (Table 5).

1 2H4MBP exposure was not associated with lower feed consumption during lactation (Table 5).  
 2 2H4MBP intake for F<sub>0</sub> females in the 3,000, 10,000, 25,000, and 50,000 ppm 2H4MBP groups,  
 3 based on feed consumption and dietary concentrations for lactation days (LDs) 1–14, was  
 4 approximately 577, 1,858, 4,460, and 12,029 mg/kg/day, respectively (Table 5).

4 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

5 Statistical significance for the vehicle control group indicates a significant trend test.

6 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

7 GD = gestation day; LD = lactation day.

8 <sup>a</sup>Data are presented as mean ± standard error (n), where n = the number of dams. Feed consumption is not reported for  
 9 nonpregnant animals during the gestation or lactation phase.

10 <sup>b</sup>Changes in n are the result of animal removal (i.e., biological sampling, animal health concerns). Additional animals removed as  
 11 outliers include: GD 6–9 (one value in the 10,000 ppm group), GD 12–15 (one value in the 25,000 ppm group), GD 18–21 (one  
 12 value in the 3,000 ppm group), and GD 6–21 (one value each in the 3,000, 10,000, and 25,000 ppm groups).

13 <sup>c</sup>Statistical analysis performed by the Jonckheere (trend) and Shirley or Dunn (pairwise) tests.

14 <sup>d</sup>Chemical intake calculated as:  $([\text{exposure concentration} \times \text{feed consumption}]/[\text{average body weight of day range}])$ .

15 <sup>e</sup>No statistical analysis performed on the chemical intake data.

## 16 **Maternal Reproductive Performance**

17 Across all exposure groups, 13 out of 57 time-mated F<sub>0</sub> females were not pregnant: four in the  
 18 control group; two each in the 3,000, 10,000, and 50,000 ppm groups; and three in the  
 19 25,000 ppm group (Table 6). There were no toxicologically relevant effects of 2H4MBP  
 20 exposure on the proportion of dams that produced viable litters or on gestation length. There was  
 21 no effect of 2H4MBP exposure on initial mean litter size or sex ratio.

1 **Table 6. Summary of the Reproductive Performance of F<sub>0</sub> Female Rats Exposed to**  
 2 **2-Hydroxy-4-methoxybenzophenone in Feed during Gestation (Dose Range-finding Study)**

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 Statistical significance for the vehicle control group indicates a significant trend test.

5 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

6 GD = gestation day; PND = postnatal day.

7 <sup>a</sup>Animals removed from the study between mating and littering were excluded from calculations of % littered females.

8 <sup>b</sup>Includes six time-mated (pregnant) rats used for biological sample collection for methods development.

9 <sup>c</sup>Excludes animal euthanized moribund on study day 5.

10 <sup>d</sup>Excludes three pregnant rats used for biological sample collection on GD 18.

11 <sup>e</sup>Percentage is the number of littered females/pregnant females. Statistical analysis performed by the Cochran-Armitage (trend) and Fisher's exact (pairwise) tests.

12 <sup>f</sup>Statistical analysis performed by the Jonckheere (trend) and Shirley or Dunn (pairwise) tests.

13 <sup>g</sup>Gestation length calculated for time-mated females that delivered a litter.

14 <sup>h</sup>Data are displayed as mean ± standard error (n).

15 <sup>i</sup>n = the number of pups examined (number of litters).

16 <sup>j</sup>Statistical analysis performed using mixed effects models with litter as a random effect for both trend and pairwise tests, and a Dunnett-Hsu adjustment for multiple pairwise comparisons.

## 19 **F<sub>1</sub> Offspring Findings**

### 20 **Pup Viability and Body Weights**

21 2H4MBP exposure was associated with a reduction in the mean number of live pups per litter in  
 22 the 25,000 and 50,000 ppm groups (approximately 2–3 pups/litter from PND 0 through PND 28)  
 23 (Table 7; Appendix E). Over the lactation period, there were 20 dead pups (from five litters) in  
 24 the 25,000 ppm group and 16 dead pups (from five litters) in the 50,000 ppm group, compared to  
 25 3 dead pups (from two litters) in the control group. In the 25,000 ppm group, 12 of the 20 dead  
 26 pups were from a single litter. In the 50,000 ppm group, 10 of the 16 dead pups were from a  
 27 single litter (Appendix E). Male and female pup mean body weights of these exposed groups  
 28 were significantly decreased (25%–50%) compared to those of control pups (Table 8; Figure 6,  
 29 Figure 7). Adverse F<sub>1</sub> pup clinical observations in the 25,000 and 50,000 ppm groups were  
 30 consistent with the effects of 2H4MBP exposure on pup survival (Appendix E). Findings  
 31 included observations of pups found dead, cannibalized, missing, no milk band, bruised, stained  
 32 fur, cold to touch, or emaciated. There were no notable gross findings in the limited number of  
 33 F<sub>1</sub> offspring that received a necropsy. Necropsy findings for pups found dead on or after PND 1

1 were limited to the absence of milk/food in the stomach (Appendix E). Pups in the 10,000 ppm  
2 group displayed mean body weights that were lower (4%–16%) than those of the control group.

1 **Exposure Concentration Selection Rationale for the Modified**  
2 **One-Generation Study of 2-Hydroxy-4-methoxybenzophenone**

3 The selection of 30,000 ppm 2H4MBP as the high exposure concentration was based on the  
4 toxicity observed at 50,000 ppm and the marginal effect on pup survival at 25,000 ppm (most of  
5 the pup deaths at this exposure concentration were attributed to a single dam). Exposure  
6 concentration spacing (3,000, 10,000, 30,000 ppm) was selected to achieve a no-observed-  
7 adverse-effect level and to avoid excessive overlap of the ingested doses due to increased feed  
8 consumption during pregnancy. The selection of the 0.05 ppm ethinyl estradiol (EE) exposure  
9 concentration as a reference positive control was informed by the National Center for  
10 Toxicological Research studies,<sup>93</sup> which demonstrated that this exposure concentration  
11 accelerated time to vaginal opening (VO), delayed time to balanopreputial separation (BPS),  
12 caused transient alterations in estrous cyclicity, and induced male mammary gland hyperplasia.

## 1 Modified One-Generation Study

### 2 F<sub>0</sub> Generation: Maternal Findings

3 Maternal effects were evaluated from GD 6 through LD 28, as shown in Figure 8. Viability,  
4 clinical observations, gestation and lactation mean body weights, feed consumption, and  
5 reproductive performance results are presented below.

6

7 **Figure 8. Design of the Modified One-Generation Study – F<sub>0</sub> Generation**

8 GD = gestation day; LD = lactation day; PND = postnatal day.

### 9 F<sub>0</sub> Viability and Clinical Observations

10 2H4MBP exposure did not affect survival of the F<sub>0</sub> females (Appendix E). One female in the EE  
11 group was removed on GD 11 and was subsequently diagnosed with lymphoma. Given the  
12 singular incidence and early onset, this death was not considered related to EE exposure. No  
13 clinical observations were attributed to 2H4MBP exposure (Appendix E).

### 14 F<sub>0</sub> Gestation Body Weights and Feed Consumption

15 F<sub>0</sub> females exposed to 10,000 or 30,000 ppm 2H4MBP displayed lower gestation mean body  
16 weights and body weight gains (Table 9; Figure 9). On GD 21, female mean body weights were  
17 significantly decreased by 5% and 10% compared to those of control animals in the 10,000 and  
18 30,000 ppm 2H4MBP groups, respectively. Body weight gains between GD 6 and GD 21 were  
19 significantly decreased by 11%, 25%, and 35% compared to those of the control group in the

1 10,000 and 30,000 ppm 2H4MBP and 0.05 ppm EE groups, respectively (Table 9). There was a  
 2 transient loss in mean body weight (-1.0 g) between GD 6 and GD 9 in the 30,000 ppm  
 3 2H4MBP group compared to a gain of 13.7 g in the control group. This interval corresponds to  
 4 the first interval the females were administered dosed feed and likely reflects lower palatability  
 5 of the dosed feed; this is also consistent with what was observed in the dose range-finding study.  
 6 Females in the 30,000 ppm groups also exhibited significantly decreased (approximately 12%)  
 7 body weight gains in the GD 15–18 and GD 18–21 intervals (Table 9). Gestational mean body  
 8 weights and weight gains in the EE group were less than those in the control group. Body weight  
 9 gain in the EE group over the GD 6–21 interval was significantly decreased by approximately  
 10 35% compared to the control group (Table 9). There was no effect of 2H4MBP exposure on  
 11 F<sub>0</sub> female mean body weights during gestation in the 3,000 ppm group. There was no reduction  
 12 in litter size on PND 0 or pup mean body weight on PND 1 in the 2H4MBP-exposed groups  
 13 (Appendix E), suggesting the lower relative maternal body weights were due to a maternal body  
 14 weight effect of 2H4MBP rather than an effect on the collective weight of the uterine contents.  
 15 Pup body weight on PND 1, but not litter size, was significantly decreased in the 0.05 ppm EE  
 16 group (Appendix E) and likely contributed to the lower maternal body weight gain of that group  
 17 compared to the control group.

20 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

21 Statistical significance for the vehicle control group indicates a significant trend test.

22 \*Statistically significant at p ≤ 0.05; \*\*p ≤ 0.01.

23 EE = ethinyl estradiol.

24 <sup>a</sup>Data are displayed as mean ± standard error (n); body weight data are presented in grams.

25 <sup>b</sup>Statistical analysis performed by the Jonckheere (trend) and Williams or Dunnett (pairwise) tests.

26 <sup>c</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

1  
2 **Figure 9. Growth Curves for F<sub>0</sub> Female Rats Exposed to 2-Hydroxy-4-methoxybenzophenone in**  
3 **Feed during Gestation**

4 EE = ethinyl estradiol. Information for statistical significance in maternal weights is provided in Table 9.

5 Despite sporadic differences, neither 2H4MBP nor EE exposure adversely affected feed  
6 consumption during gestation (Table 10). Observed higher feed consumption in the 30,000 ppm  
7 group likely represented feed wastage. 2H4MBP intake for F<sub>0</sub> females in the 3,000, 10,000, and  
8 30,000 ppm groups, based on feed consumption and dietary concentrations over the GD 6–21  
9 interval, was approximately 205, 697, and 2,644 mg/kg/day, respectively (Table 10). EE intake  
10 during gestation was approximately 0.004 mg/kg/day.

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 Statistical significance for the vehicle control group indicates a significant trend test.

5 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

6 EE = ethinyl estradiol; GD = gestation day.

7 <sup>a</sup>Data are displayed as mean ± standard error (n), where n = the number of dams. Feed consumption is not reported for  
 8 nonpregnant animals during the gestation phase.

9 <sup>b</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

10 <sup>c</sup>Statistical analysis performed by the Jonckheere (trend) and Shirley or Dunn (pairwise) tests.

11 <sup>d</sup>Change in n is due to the exclusion of improbable data.

12 <sup>e</sup>Excludes one dam euthanized moribund on GD 11.

13 <sup>f</sup>Excludes feed consumption from cages where excess feed spillage was observed.

14 <sup>g</sup>Chemical intake calculated as: ([exposure concentration × feed consumption]/[average body weight of day range]).

15 <sup>h</sup>No statistical analysis performed on the chemical intake data.

16 <sup>i</sup>EE intake presented as  $\mu\text{g}/\text{kg}/\text{day}$ .

## 17 **Maternal Reproductive Performance**

18 Across all exposure groups, 20 of 125 time-mated rats were not pregnant: three each in the  
 19 control and 10,000 ppm groups, four in the 3,000 ppm group, five in the 30,000 ppm group, and  
 20 five in the EE group (Table 11; Appendix E). There was no effect of 2H4MBP exposure on the  
 21 proportion of dams that produced viable litters or on gestation length. There was no effect of  
 22 2H4MBP exposure on initial mean litter size, PND 1 pup weight, or sex ratio. PND 1 pup weight  
 23 in the EE group was significantly decreased by 13% compared to the control group (Table 11).  
 24 Anogenital distance (AGD) measurements are presented in Appendix E.

1 **Table 11. Summary of the Reproductive Performance of F<sub>0</sub> Female Rats Exposed to**  
 2 **2-Hydroxy-4-methoxybenzophenone in Feed during Gestation**

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 Statistical significance for the vehicle control group indicates a significant trend test.

5 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

6 EE = ethinyl estradiol; GD = gestation day; PND = postnatal day.

7 <sup>a</sup>Animals removed from the study between mating and littering were excluded from calculations of % littered females.

8 <sup>b</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

9 <sup>c</sup>Percentage is the number of littered females/pregnant females. Statistical analysis performed by the Cochran-Armitage (trend)  
 10 and Fisher's exact (pairwise) tests.

11 <sup>d</sup>Excludes one dam euthanized moribund on GD 11.

12 <sup>e</sup>Statistical analysis performed by the Jonckheere (trend) and Shirley or Dunn (pairwise) tests.

13 <sup>f</sup>Gestation length was calculated for time-mated females that delivered a litter.

14 <sup>g</sup>Data are displayed as mean ± standard error (n).

15 <sup>h</sup>n = the number of pups examined (number of litters).

16 <sup>i</sup>Statistical analysis performed using mixed effects models with litter as a random effect for both trend and pairwise tests, and a  
 17 Dunnett-Hsu adjustment for multiple pairwise comparisons.

18 <sup>j</sup>Excludes one litter in which the lone pup died on PND 1.

## 19 **Lactation Body Weights and Feed Consumption**

20 F<sub>0</sub> females in the 10,000 and 30,000 ppm 2H4MBP and 0.5 ppm EE groups displayed lower  
 21 mean body weights during lactation compared to the control group (Figure 10; Table 12). The  
 22 magnitude of response in female body weights at LD 1 and LD 28 was similar to that observed at  
 23 the end of the gestation interval. There was no effect of 2H4MBP or EE exposure on body  
 24 weight gain during the lactation interval. These observations collectively suggest that the lower  
 25 lactation body weight was a consequence of exposure to 2H4MBP or EE during gestation and  
 26 not a direct effect of exposure during lactation.

27 Feed consumption during lactation was similar among the groups. Dam 2H4MBP intake based  
 28 on feed consumption and dietary concentrations during lactation from LD 1 through LD 13 (until  
 29 the pups started consuming feed) for the 3,000, 10,000, and 30,000 ppm groups was  
 30 approximately 484, 1,591, and 5,120 mg/kg/day, respectively (Table 12). EE intake during  
 31 lactation was approximately 0.008 mg/kg/day.

10 <sup>c</sup>Statistical analysis performed by the Jonckheere (trend) and Williams or Dunnett (pairwise) tests.

11 <sup>d</sup>Excludes body weights of two dams on lactation day (LD) 4 and one dam on LD 7 scheduled for removal.

12 <sup>e</sup>Statistical analysis performed by the Jonckheere (trend) and Shirley or Dunn (pairwise) tests.

13 <sup>f</sup>Chemical intake calculated as:  $([\text{exposure concentration} \times \text{feed consumption}]/[\text{average body weight of day range}])$ .

14 <sup>g</sup>No statistical analysis performed on the chemical intake data.

15 <sup>h</sup>EE intake presented as  $\mu\text{g}/\text{kg}/\text{day}$ .

○ 0 ppm ▲ 3,000 ppm ■ 10,000 ppm ◇ 30,000 ppm ▼ 0.05 ppm EE

1  
2 **Figure 10. Growth Curves for F<sub>0</sub> Female Rats Exposed to 2-Hydroxy-4-methoxybenzophenone in**  
3 **Feed during Lactation**

4 EE = ethinyl estradiol. Information for statistical significance in maternal weights is provided in Table 12.

5 Collectively, these data indicate that 30,000 ppm 2H4MBP and 0.05 ppm EE challenged the  
6 dams (as demonstrated by significantly decreased GD 6–21 body weights), without adversely  
7 affecting F<sub>1</sub> litter size.

## 1 **F<sub>1</sub> Generation: Prewearing**

2 F<sub>1</sub> male and female rats were evaluated during the preweaning period from PND 0 through  
 3 PND 28, as shown in Figure 11. Viability, clinical observations, and mean body weight results  
 4 are presented below.

5

6 **Figure 11. Design of the Modified One-Generation Study – F<sub>1</sub> Generation: Prewearing**

7 GD = gestation day; LD = lactation day; PND = postnatal day.

## 8 **F<sub>1</sub> Viability and Clinical Observations**

9 Clinical observations were noted in individual pups in all groups, including the control groups,  
 10 and were typically indicative of a pup not thriving (e.g., cold to the touch, no milk in the  
 11 stomach) (Appendix E). There was no effect of 2H4MBP on pup survival (Table 13). The mean  
 12 number of live pups per litter appeared to be reduced in the 0.05 ppm EE group on PND 4  
 13 relative to the control group. That reduction reflected three litters that did not survive to PND 4,  
 14 resulting in a higher number of dead or missing (presumed dead) pups and a lower survival ratio  
 15 for the PND 1–4 interval relative to the control group. On PND 28, there was a slight, but  
 16 significant, decrease in mean litter size in the EE group relative to the control group.

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 <sup>\*\*</sup>Statistically significant at  $p \leq 0.01$ .

5 EE = ethinyl estradiol.

6 <sup>a</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

7 <sup>b</sup>n = the number of pups examined (number of litters).

8 <sup>c</sup>Data are displayed as mean ± standard error of the litter means (n), where n = the number of litters. For F<sub>1</sub> pups, data are  
 9 displayed as the mean of litter values ± standard error (n) of litter values (number of litters produced by F<sub>0</sub> dams).

10 <sup>d</sup>F<sub>1</sub> litter size and survival endpoints were analyzed using the Jonckheere (trend) and Shirley or Dunn tests (pairwise  
 11 comparisons). All calculations were based on the last litter observation of the day.

12 <sup>e</sup>One whole litter loss occurred by postnatal day (PND) 1.

13 <sup>f</sup>Three whole litter losses occurred by PND 4 (one by PND 1).

**1 F<sub>1</sub> Body Weights****2 Male Pups**

3 An exposure concentration- and time-related reduction in male pup mean body weight per litter  
4 was observed during lactation in the 10,000 and 30,000 ppm 2H4MBP and the 0.05 ppm EE  
5 groups, relative to the control group (Table 14; Figure 12). From PND 1 through PND 28, mean  
6 body weight differences were significantly increased between the control group and the  
7 30,000 ppm group and, to a lesser extent, the 10,000 ppm group. On PND 28, male pup mean  
8 body weights per litter were significantly decreased by 10%, 24%, and 11% compared to those  
9 of the control group in the 10,000 and 30,000 ppm 2H4MBP and 0.05 ppm EE groups,  
10 respectively.

**11 Female Pups**

12 An exposure concentration- and time-related reduction in female pup mean body weight per litter  
13 was observed during lactation in the groups exposed to 10,000 or 30,000 ppm 2H4MBP and  
14 0.05 ppm EE, relative to the control group (Table 14; Figure 13). From PND 1 through PND 28,  
15 mean body weight differences became greater between the control group and the 30,000 ppm  
16 group and, to a lesser extent, the 10,000 ppm group. On PND 28, female pup mean body weights  
17 per litter were significantly decreased by 9%, 24%, and 7% compared to those of the control  
18 group in the 10,000 and 30,000 ppm 2H4MBP and 0.05 ppm EE groups, respectively.

2 **Figure 12. Lactation Growth Curves for F<sub>1</sub> Male Pups Following Perinatal Exposure to**  
3 **2-Hydroxy-4-methoxybenzophenone**

4 EE = ethinyl estradiol. Information for statistical significance in male pup weights is provided in Table 14.

5  
6 **Figure 13. Lactation Growth Curves for F<sub>1</sub> Female Pups Following Perinatal Exposure to**  
7 **2-Hydroxy-4-methoxybenzophenone**

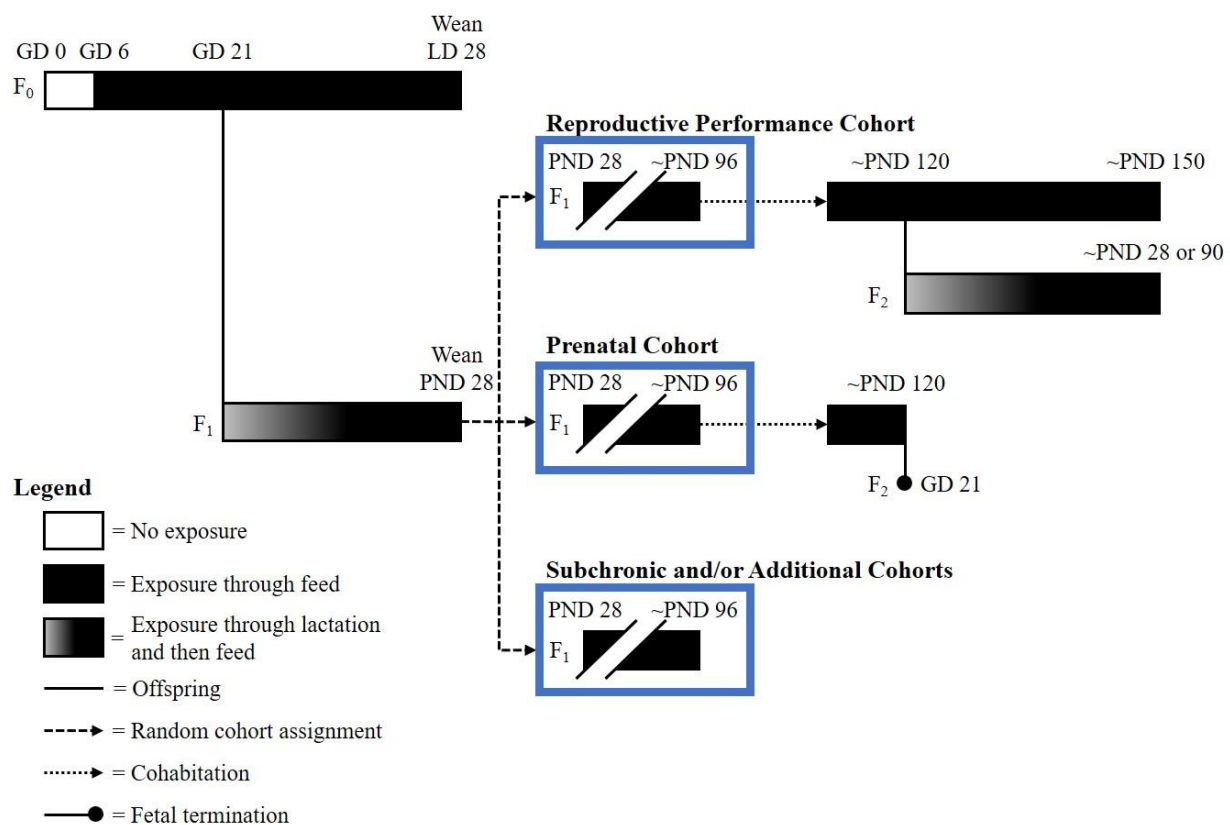

8 EE = ethinyl estradiol. Information for statistical significance in female pup weights is provided in Table 14.

## 1 **F<sub>0</sub> Necropsy**

2 F<sub>0</sub> dams were necropsied on PND 28 following pup weaning when the F<sub>0</sub> dams were 21 weeks of  
 3 age. Gross findings of pale, discolored kidneys (unilateral/bilateral) were recorded for three  
 4 females in the 30,000 ppm 2H4MBP group (Appendix E). Histopathological examination  
 5 identified findings of renal tubule lumen dilatation, tubule epithelium regeneration, interstitial  
 6 inflammation, papilla necrosis, nephropathy, and transitional epithelium hyperplasia. Similar  
 7 findings were also observed in the F<sub>1</sub> and F<sub>2</sub> generations exposed to 2H4MBP (Appendix E).

## 8 **F<sub>1</sub> Generation: Postweaning through Sexual Maturity**

9 F<sub>1</sub> male and female rats were evaluated from postweaning through sexual maturity, as shown in  
 10 Figure 14. Viability, clinical observations, mean body weights, feed consumption, and  
 11 developmental endpoint results are presented below.

12

13 **Figure 14. Design of the Modified One-Generation Study – F<sub>1</sub> Generation: Postweaning**

14 GD = gestation day; LD = lactation day; PND = postnatal day.

## 15 **F<sub>1</sub> Viability and Clinical Observations**

16 Neither 2H4MBP nor EE exposure altered viability in the F<sub>1</sub> generation postweaning. Clinical  
 17 observations were noted in all groups, including the control groups, on a sporadic basis  
 18 (Appendix E). No clinical observations showed an increase in incidence or severity in  
 19 association with exposure to 2H4MBP or EE.

## 1 **F<sub>1</sub> Body Weights and Feed Consumption**

### 2 ***Males (Postweaning)***

3 Body weights between PND 28 and PND 91 were significantly decreased in males in the 10,000  
4 and 30,000 ppm 2H4MBP and 0.05 ppm EE groups (Table 15; Figure 15). On PND 91, mean  
5 body weights of these groups were significantly decreased by 5%, 16%, and 18%, respectively,  
6 compared to those of the control group.

7 Overall, no adverse effects of 2H4MBP exposure on F<sub>1</sub> male feed consumption were found  
8 (Table 15). Sporadic small but significant decreases in absolute feed consumption (g/animal/day)  
9 were observed in the 30,000 ppm group between PND 28 and PND 84 (Appendix E) but did not  
10 affect overall feed consumption during the postweaning period. Relative feed consumption  
11 (g/kg/day) was significantly increased in the 10,000 and 30,000 ppm groups relative to the  
12 control group during the postweaning period, likely due to the lower body weights of the animals  
13 in these groups. A significant decrease in absolute feed consumption was observed in the  
14 0.05 ppm EE group (14% below the control group) during the postweaning period, suggesting a  
15 continued effect of EE exposure on growth during the postweaning phase. 2H4MBP intake for  
16 F<sub>1</sub> males, based on feed consumption and dietary concentrations for PND 28 through PND 91,  
17 was approximately 267, 948, and 3,003 mg/kg/day at 3,000, 10,000, and 30,000 ppm 2H4MBP,  
18 respectively (Table 15). EE intake during the postweaning period was approximately  
19 0.005 mg/kg/day.

15 <sup>h</sup>No statistical analysis performed on the chemical intake data.

16 <sup>i</sup>EE intake presented as  $\mu\text{g}/\text{kg}/\text{day}$ .

1 **○ 0 ppm ▲ 3,000 ppm ■ 10,000 ppm ◇ 30,000 ppm ▼ 0.05 ppm EE**  
 2 **Figure 15. Postweaning Growth Curves for All F<sub>1</sub> Male Rats Exposed to**  
 3 **2-Hydroxy-4-methoxybenzophenone in Feed**

4 EE = ethinyl estradiol. Information for statistical significance in F<sub>1</sub> male rat weights is provided in Table 15.

#### 5 **Females (Postweaning)**

6 PND 28 through PND 91 mean body weights were significantly decreased in females exposed to  
 7 30,000 ppm 2H4MBP or 0.05 ppm EE (Table 16; Figure 16). On PND 91, female mean body  
 8 weights of the 30,000 ppm 2H4MBP and 0.05 ppm EE groups were significantly decreased by  
 9 14% and 17%, respectively, compared to those of the control group. The 10,000 ppm group  
 10 displayed significantly decreased mean body weights (<10%) on PND 28 and PND 35 (Table 16;  
 11 Appendix E), after which mean body weights were similar to those of the control group.

12 In general, 2H4MBP-exposed females displayed similar feed consumption values over the  
 13 postweaning period (Table 16; Appendix E). There were small (approximately 15%), but  
 14 significant, increases in absolute feed consumption (g/animal/day) recorded over two weekly  
 15 intervals in the 30,000 ppm 2H4MBP group between PND 42 and PND 91. There was no overall  
 16 reduction in absolute feed consumption during the postweaning period in the 30,000 ppm  
 17 2H4MBP group. Relative feed consumption (g/kg/day) was significantly increased in the  
 18 30,000 ppm group relative to the control group during the postweaning period, likely the result  
 19 of lower body weights of the 2H4MBP-exposed animals. Absolute feed consumption by the EE  
 20 group was similar to the control group; however, as these animals weighed less, their relative  
 21 feed consumption was significantly increased compared to that of the control animals. 2H4MBP  
 22 intake for F<sub>1</sub> females, based on feed consumption and dietary concentrations for PND 28  
 23 through PND 91, was approximately 287, 983, and 3,493 mg/kg/day at 3,000, 10,000, and  
 24 30,000 ppm 2H4MBP exposures, respectively. EE intake during the postweaning period was  
 25 approximately 0.005 mg/kg/day.

2 **Figure 16. Postweaning Growth Curves for All F<sub>1</sub> Female Rats Exposed to**  
 3 **2-Hydroxy-4-methoxybenzophenone in Feed**

4 EE = ethinyl estradiol. Information for statistical significance in F<sub>1</sub> female rat weights is provided in Table 16.

## 5 **Developmental Endpoints**

### 6 **Anogenital Distance**

7 F<sub>1</sub> and F<sub>2</sub> male and female offspring exposed to 2H4MBP or EE in feed did not display any  
 8 alterations in mean PND 1 body-weight-adjusted AGD (Appendix E).

### 9 **Areolae/Nipple Retention**

10 F<sub>1</sub> and F<sub>2</sub> male offspring exposed to 2H4MBP or EE in feed did not display any signs of  
 11 areolae/nipple retention (Appendix E).

### 12 **Testicular Descent**

13 F<sub>1</sub> males in the 30,000 ppm 2H4MBP group displayed a significant 1-day acceleration in the  
 14 mean day of testicular descent ( $18.0 \pm 0.2$ ) compared to the control group ( $19.1 \pm 0.2$ )  
 15 (Appendix E). There was no difference in the mean day of testicular descent in the F<sub>2</sub> generation  
 16 (Appendix E). The cumulative litter responses for the 30,000 ppm 2H4MBP group  
 17 (F<sub>1</sub> generation) showed an earlier age at acquisition, whereas the F<sub>2</sub> generation did not display  
 18 this response. The mean day of achieving testicular descent in control Sprague Dawley  
 19 (Hsd:Sprague Dawley<sup>®</sup> SD<sup>®</sup>) rats in two other MOG studies conducted in the testing laboratory  
 20 was PND  $18.2 \pm 0.2$  and PND  $18.0 \pm 0.2$ . For NTP Reproductive Assessment by Continuous  
 21 Breeding (RACB) studies, the mean day of testicular descent ranged from PND  $15.3 \pm 0.2$  to  
 22 PND  $17.4 \pm 0.5$  over four studies.<sup>94;95</sup>

## 1 Vaginal Opening

2 Females exposed to 30,000 ppm 2H4MBP exhibited a significant delay in litter mean day of VO,  
 3 relative to the control group (Table 17); however, when adjusted for body weight at weaning,  
 4 this delay was somewhat mitigated, with the 30,000 ppm group displaying a 1-day delay.  
 5 Figure 17 shows litter and adjusted litter cumulative response (%), or cumulative probability of  
 6 attainment, plotted against PND for each exposure group. Exposure increases were associated  
 7 with higher cumulative probabilities of attainment delays, particularly for the 30,000 ppm group,  
 8 as seen in the exposure-related rightward shift of curves toward higher attainment days  
 9 (Figure 17). These shifts were less pronounced after adjustment for body weight at weaning  
 10 (Figure 17). The delay was associated with lower body weight, and these females also exhibited  
 11 significantly decreased mean body weights during lactation and postweaning (Table 16;  
 12 Figure 16). As expected, litter mean day of VO in the EE group was greatly accelerated (by  
 13 approximately 11 days) compared to the control group (Table 17; Figure 17).

16 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

17 Statistical significance for the vehicle control group indicates a significant trend test.

18 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

19 EE = ethinyl estradiol; VO = vaginal opening.

20 <sup>a</sup>Data are displayed as mean ± standard error unless otherwise noted; values are based on litter means, not individual pup values.

21 <sup>b</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

22 <sup>c</sup>No. Examined = the number of pups examined (number of litters).

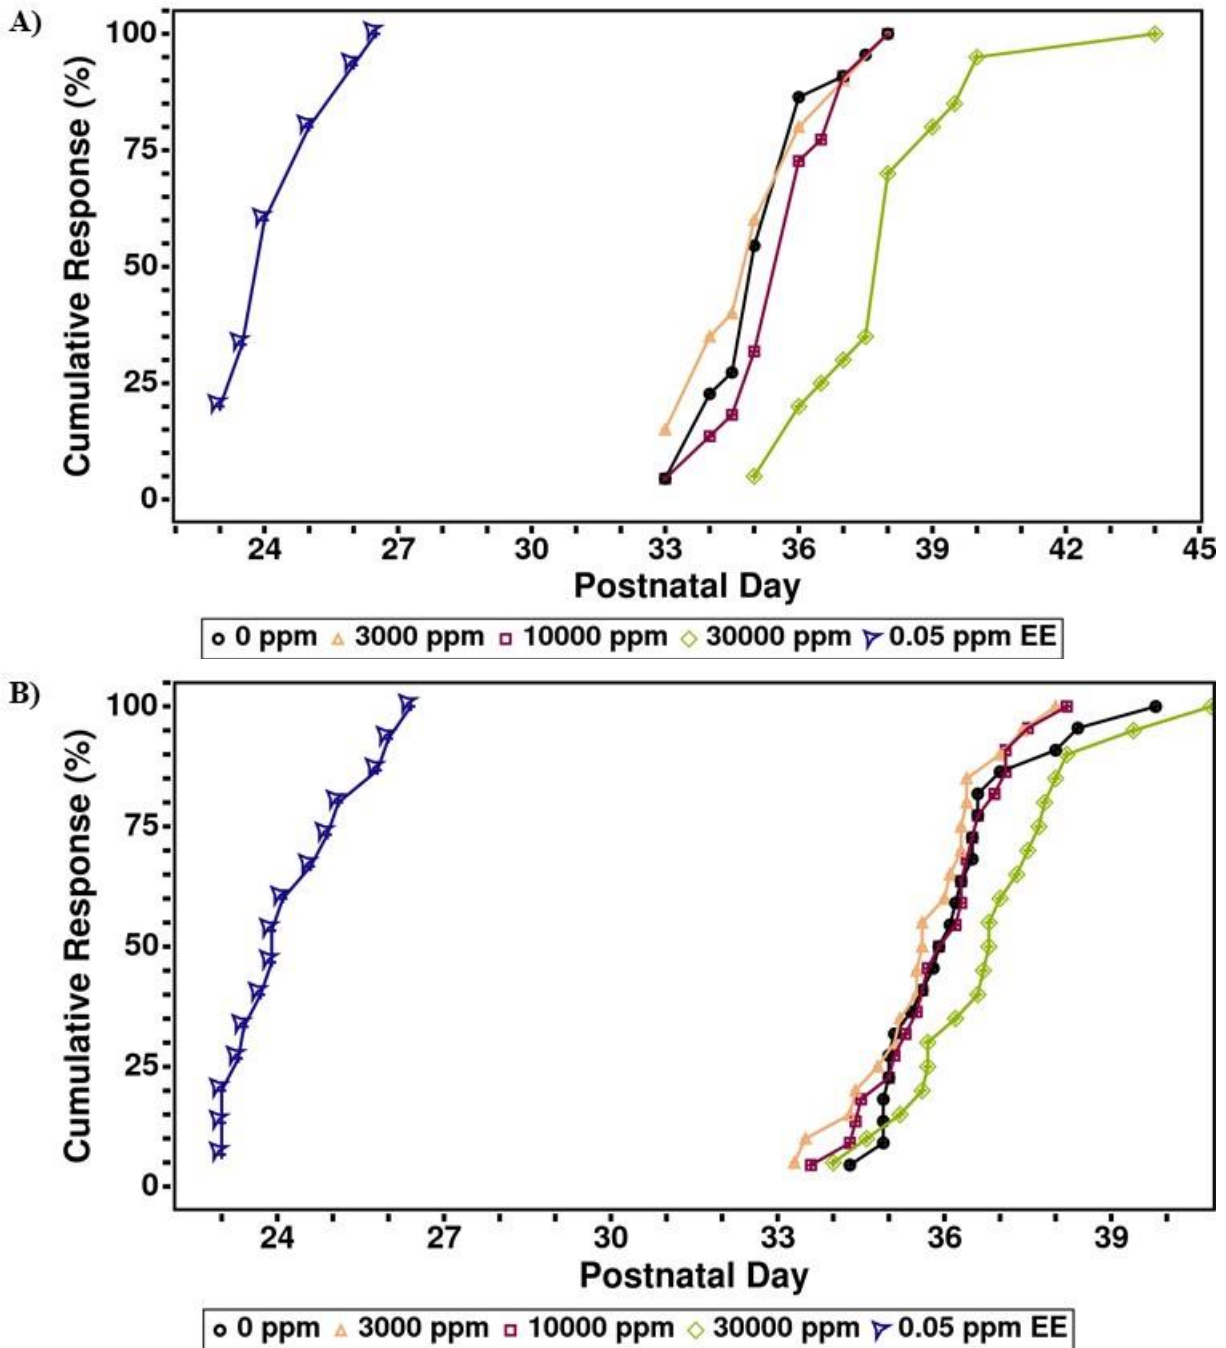

23 <sup>d</sup>No. Not Attaining = number of pups that survived to the end of the observation period without attaining VO.

24 <sup>e</sup>Summary statistics and mixed model results are presented for animals that attained during the observation period.

25 <sup>f</sup>Statistical analysis performed using mixed effects models with litter as a random effect for both trend and pairwise tests, and a  
 26 Dunnett-Hsu adjustment for multiple pairwise comparisons.

27 <sup>g</sup>Adjusted based on body weight at weaning.

28 <sup>h</sup>Analysis of body weight at acquisition and body weight at weaning for both linear trend and pairwise comparisons performed  
 29 using mixed effects models with litter as a random effect and a Dunnett-Hsu adjustment for multiple pairwise comparisons.

**Figure 17. Time to Vaginal Opening of F<sub>1</sub> Female Offspring Exposed to 2-Hydroxy-4-methoxybenzophenone in Feed**

EE = ethinyl estradiol. (A) Litter response and (B) litter response adjusted for body weight at weaning.

## 1 **Balanopreputial Separation**

2 Male rats in the 10,000 and 30,000 ppm 2H4MBP and 0.05 ppm EE groups displayed a  
 3 significant delay in the mean day of attaining BPS (Table 18). Figure 18 shows litter and  
 4 adjusted litter cumulative response (%), or cumulative probability of attainment, plotted against  
 5 PND for each exposure group. An exposure-dependent rightward shift is seen for the 10,000 and  
 6 30,000 ppm 2H4MBP and 0.05 ppm EE groups, indicating higher cumulative probabilities of  
 7 attainment at later PNDs (Figure 18). When litter mean day of attainment was adjusted for body  
 8 weight on day of weaning, these delays were no longer significantly different from control males  
 9 (Table 18; Figure 18). The observed delay in BPS in 2H4MBP- or EE-exposed animals is likely  
 10 the consequence of growth retardation as evidenced by lower mean body weights and body  
 11 weight gains (Table 15; Figure 15). Three males in the 30,000 ppm 2H4MBP group had not  
 12 achieved BPS as of PND 59, when checks for this marker stopped. These males were from the  
 13 same litter (dam 202). Two were assigned to the reproductive performance cohort (animals 1901  
 14 and 1907) and the other (animal 1903) was assigned to the prenatal cohort. None of them  
 15 demonstrated evidence of mating or resultant evidence of pregnancy. At scheduled necropsy, two  
 16 of the males had achieved BPS and the other (animal 1903) had a hypospadias.

## 1 F<sub>1</sub> Cohort Data

### 2 Prenatal and Reproductive Performance Cohorts: Mating and Fertility

3 F<sub>1</sub> male and female rats from the prenatal and reproductive performance cohorts were mated and  
 4 evaluated for reproductive endpoints, as shown in Figure 19. Viability, clinical observations,  
 5 vaginal cytology, fertility, andrology, mean body weights, and feed consumption results are  
 6 presented below.

7

8 **Figure 19. Design of the Modified One-Generation Study – Prenatal and Reproductive**  
 9 **Performance Cohorts**

10 GD = gestation day; LD = lactation day; PND = postnatal day.

### 11 Viability and Clinical Observations

12 There were no exposure-related deaths or clinical observations in F<sub>1</sub> male and female rats  
 13 following exposure to 2H4MBP or EE in feed (Appendix E).

### 14 Selection and Mating

15 A male and a female, or two males and two females (1:1), from each litter were allocated to the  
 16 prenatal and reproductive performance cohorts, respectively, avoiding sibling mating  
 17 (Figure 19). Vaginal lavage samples were collected for approximately 2 weeks prior to  
 18 cohabitation and continued until evidence of mating or until the cohabitation period was  
 19 completed. Estrous cyclicity data are presented in Appendix E.

## 1 **Vaginal Cytology**

2 Rats in the 10,000 and 30,000 ppm 2H4MBP groups of both cohorts displayed a higher  
3 probability of extended estrus (Appendix E) and spent approximately 5% more time in estrus  
4 than did the control group. Analysis of estrous cyclicity using the continuous-time Markov  
5 model resulted in an increase in the stage length of estrus in the 10,000 and 3,000 ppm groups  
6 (approximately 5 hours), but only attained significance relative to the control group in the  
7 10,000 ppm group. A significant decrease in the length of proestrus (approximately 2 hours) was  
8 observed in the 10,000 ppm group. These minimal estimated changes in stage length likely  
9 represent normal biological variability and are not considered biologically adverse. There were  
10 no EE exposure-related changes in estrous stage lengths.

## 11 **Fertility**

12 The precoital interval and number of females that mated (i.e., those that were sperm-positive,  
13 littered, or had implantation sites) were similar among the control, 2H4MBP, and EE groups in  
14 both cohorts, indicating that neither 2H4MBP nor EE exposure negatively affected mating  
15 behavior (Table 19). The number of pregnant females was also similar among the groups,  
16 indicating that F<sub>1</sub> male and female fertility were not affected by 2H4MBP or EE exposure at the  
17 concentrations examined. Respective responses observed were consistent between the cohorts.

## 18 **F<sub>1</sub> Reproductive Performance Cohort Andrology**

19 There were no 2H4MBP- or EE-related effects on motile sperm, progressively motile sperm, or  
20 testis spermatid head concentration (Appendix E). Males in the 30,000 ppm 2H4MBP group  
21 displayed lower cauda epididymal sperm counts (approximately 14%) and epididymis weight  
22 (approximately 6%) relative to control animals. Testis weight was lower in the 10,000 and  
23 30,000 ppm 2H4MBP and 0.05 ppm EE groups (approximately 6%, 6%, and 9%, respectively),  
24 relative to control animals. These findings were not associated with histopathological changes  
25 (Appendix E) or significant changes in reproductive performance (Appendix E).

## 26 **Gestation Body Weights**

27 As previously mentioned, F<sub>1</sub> female rats exposed to 10,000 or 30,000 ppm 2H4MBP or 0.05 ppm  
28 EE displayed significantly decreased preweaning and postweaning mean body weights compared  
29 to the control group. Consequently, F<sub>1</sub> female mean body weights of the 30,000 ppm 2H4MBP  
30 and 0.05 ppm EE groups in both the prenatal and reproductive performance cohorts at the time of  
31 cohabitation were lower relative to control females. Gestation body weight curves of the exposed  
32 groups in both cohorts generally paralleled the control group (Figure 20, Figure 21). Dams in  
33 both cohorts exposed to 10,000 or 30,000 ppm 2H4MBP or 0.05 ppm EE, however, displayed  
34 significantly decreased GD 0–21 mean body weight gains (approximately 13%–14%, 25%–28%,  
35 and 22%–24%, respectively) relative to the respective control group (Table 20). This difference  
36 in mean body weight gain during pregnancy might be the result of a slight reduction in litter size  
37 of one to two fewer fetuses/pups observed in these groups (Appendix E). Respective responses  
38 observed were consistent between the two cohorts.

## 39 **Gestation Feed Consumption**

40 2H4MBP groups displayed similar absolute feed consumption (g/animal/day) during gestation as  
41 the respective control group. Relative feed consumption (g/kg/day) during gestation in the 3,000  
42 and 10,000 ppm 2H4MBP groups was similar to the respective control group (Table 21;  
43 Appendix E). Pregnant females in the 30,000 ppm group of the prenatal cohort displayed a

1 significant increase in relative feed consumption between GD 0 and GD 21 (approximately  
2 21%), but this is likely the result of the substantially lower body weights of this group. In the EE  
3 group of the reproductive performance cohort, absolute feed consumption between GD 0 and  
4 GD 21 was significantly decreased by approximately 19%, and relative feed consumption was  
5 similar to that of the control group. The opposite was true for the EE group in the prenatal  
6 cohort, in which relative feed consumption was significantly increased by approximately 25%  
7 relative to the control group. 2H4MBP intake of both cohorts during gestation, based on feed  
8 consumption and dietary concentrations, was approximately 240, 825, and 2,760 mg/kg/day at  
9 exposure concentrations of 3,000, 10,000, and 30,000 ppm 2H4MBP, respectively. EE intake  
10 was approximately 0.004 mg/kg/day. The respective dose consumed was similar between the two  
11 cohorts.

- 1 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group. Statistical significance for the vehicle control group  
2 indicates a significant trend test.  
3 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .  
4 GD = gestation day; EE = ethinyl estradiol; RPC = reproductive performance cohort; PC = prenatal cohort.  
5 <sup>a</sup>Data are displayed as mean ± standard error (n), where n = number of litters. Consumption is not reported for the nonpregnant animals during gestation and lactation.  
6 <sup>b</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.  
7 <sup>c</sup>Statistical analysis of the RPC cohort performed using a bootstrapped Jonckheere test for trend, and a Datta-Satten modified Wilcoxon test with Hommel adjustment for pairwise  
8 comparisons. Statistical analysis of the PC performed using the Jonckheere (trend) and Shirley or Dunn (pairwise) tests.  
9 <sup>d</sup>Chemical intake calculated as:  $(\text{exposure concentration} \times \text{feed consumption}) / [\text{average body weight of day range}]$ .  
10 <sup>e</sup>No statistical analysis was performed on the chemical intake data.  
11 <sup>f</sup>EE intake presented as  $\mu\text{g}/\text{kg}/\text{day}$ .

## 1 Prenatal Cohort Findings

- 2 F<sub>1</sub> rats and F<sub>2</sub> fetuses from the prenatal cohort were evaluated for maternal reproductive  
 3 performance and fetal findings, respectively, as shown in Figure 22.

4

## 5 Figure 22. Design of the Modified One-Generation Study – Prenatal Cohort

6

GD = gestation day; LD = lactation day; PND = postnatal day.

## 7 Maternal Reproductive Performance and Uterine Data

8 In the prenatal cohort, females were between 109 and 132 days of age at the time of laparotomy.  
 9 Pregnant females exposed to 10,000 or 30,000 ppm 2H4MBP displayed lower gravid uterine  
 10 weights (15% and 17%, respectively), fewer implants, and fewer live fetuses (approximately  
 11 2 fewer/litter) than control animals; significant decreases were observed for gravid uterine  
 12 weight and number of implantations at 30,000 ppm (Table 22). In the 30,000 ppm 2H4MBP  
 13 group, these findings correlated with significant decreases in the mean number of corpora lutea  
 14 (approximately 4 fewer/litter) relative to the control group and are consistent with the reduction  
 15 in live litter size on PND 0 relative to control animals observed in the reproductive performance  
 16 cohort (Appendix E). Females in the 0.05 ppm EE group exhibited significantly decreased gravid  
 17 uterine weight (20% lower than the control group), mean number of corpora lutea, implantations,  
 18 and live fetuses (Table 22). Dams exposed to 2H4MBP or EE did not display any adverse  
 19 changes in postimplantation loss, mean live fetal weights, or fetal sex ratio.

1 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

2 Statistical significance for the vehicle control group indicates a significant trend test.

3 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

4 EE = ethinyl estradiol; GD = gestation day.

5 <sup>a</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

6 <sup>b</sup>Statistical analysis performed by the Cochran-Armitage (trend) and Fisher's exact (pairwise) tests.

7 <sup>c</sup>Includes animals that had any evidence of pregnancy but were removed from the study before GD 21.

8 <sup>d</sup>Data are reported per litter as mean ± standard error (n) and do not include nonmated, nonpregnant, or unexamined animals or  
9 those that did not survive to the end of the study.

10 <sup>e</sup>Statistical analysis performed by the Jonckheere (trend) and Shirley or Dunn (pairwise) tests.

11 <sup>f</sup>Includes two dams with total litter loss.

12 <sup>g</sup>n = the number of pups examined (number of litters).

13 <sup>h</sup>Statistical analysis performed by the Jonckheere (trend) and Williams or Dunnett (pairwise) tests.

14 <sup>i</sup>Body weight adjusted for gravid uterus weight.

## 15 Fetal Findings

### 16 Placental Morphology

17 There was no effect of 2H4MBP or EE exposure on the incidence of placental abnormalities  
18 (Appendix E). Fused placentae between two adjacent fetuses were noted for a single litter in the  
19 control group and the 10,000 ppm 2H4MBP group. Fused placentae were observed in two litters  
20 in the 30,000 ppm 2H4MBP group; one litter had a fusion between two adjacent fetuses, and the  
21 other litter had multiple fused placentae. The significant increase in incidence in placental  
22 abnormalities in the 30,000 ppm group was not considered 2H4MBP-related as most of the  
23 fusions were limited to a single litter and fused placentae have been observed in control litters of  
24 different stocks of Sprague Dawley rats.

### 25 External

26 There was no effect of 2H4MBP or EE at the exposures tested on the incidence of fetal external  
27 abnormalities (Appendix E), which were limited to a single fetus in the 30,000 ppm group that  
28 displayed anal atresia, clubbed hind limbs, tail agenesis, and a hematoma on the torso. This fetus  
29 also had multiple visceral and skeletal abnormalities.

### 30 Visceral

31 Male and female fetuses (combined) exposed to 30,000 ppm 2H4MBP displayed a higher  
32 incidence of enlarged liver, a malformation (Table 23), which had not been observed in NTP  
33 historical controls.

1 The 30,000 ppm 2H4MBP group displayed a higher incidence of unilateral or bilateral  
2 (combined) hydronephrosis, a malformation, relative to the control group (Table 23). This higher  
3 incidence was observed in 2.22% of the fetuses (29.41% of the litters), whereas it was observed  
4 in 1.12% and 1.15% of the fetuses (16.67% and 13.33% of the litters) from the control group and  
5 EE group, respectively. The NTP historical control range for unilateral or bilateral  
6 hydronephrosis is 0.00% to 0.81% for fetuses; (0.00% to 16.67% for litters). The incidence of  
7 bilateral distended ureter, a variation, was higher in all 2H4MBP-exposed groups as well as the  
8 EE group, relative to the control group. When unilateral and bilateral distended ureters were  
9 combined, the fetal incidence was 10.68%, 12.72%, and 8.44% (62.50%, 50.00%, and 35.29% of  
10 the litters) in the 3,000, 10,000, and 30,000 ppm groups versus 4.83% and 12.64% (44.44% and  
11 46.67% of the litters) in the control and EE groups, respectively. Historical control incidence for  
12 distended ureter in fetuses is 10.90% (4.83% to 15.36%) and for litters is 56.70% (43.75% to  
13 68.18%). Hydroureter of the left kidney was observed in one fetus in the control group and in  
14 two fetuses in the 3,000 ppm group, but given the low incidence, these were not considered  
15 related to 2H4MBP exposure (Appendix E). The NTP historical control range for hydroureter is  
16 up to 2.83% and 21.05% for fetuses and litters, respectively. Hydronephrosis and other  
17 abnormalities associated with the kidney and ureter (e.g., dilated renal pelvis, distended ureter,  
18 hydroureter) are common findings in this strain of rat; therefore, these collective findings may or  
19 may not be related to the 2H4MBP-associated microscopic findings observed in the kidney of  
20 adult F<sub>1</sub> males and females exposed to 30,000 ppm 2H4MBP (Appendix E).

21 Other malformations observed in 2H4MBP-exposed fetuses include ventricular septal defects in  
22 two fetuses in the 10,000 ppm group and in one fetus in the 30,000 ppm group (Table 23). This  
23 finding was not considered related to 2H4MBP due to the low incidence and lack of a clear  
24 exposure concentration-response and because it had been observed in a control fetus in a  
25 previous study (1/1,385). A single fetus (dam 1950, fetus 01) in the 30,000 ppm 2H4MBP group  
26 displayed adrenal gland agenesis, malpositioned kidneys, distended stomach, and agenesis of the  
27 gonads (Appendix E). This fetus also had external and skeletal malformations. None of the  
28 visceral findings associated with this fetus was considered 2H4MBP-related due to their singular  
29 occurrence. One fetus in the 10,000 ppm group displayed small, round kidneys, which were not  
30 considered 2H4MBP-related due to the singular occurrence.

31 There were no additional effects of EE exposure on the incidence of fetal visceral variations.

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 <sup>#</sup>Statistically significant at  $p \leq 0.05$  (litter-based analysis).

5 EE = ethinyl estradiol; [M] = malformation; [V] = variation.

6 <sup>a</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

7 <sup>b</sup>Upper row denotes number of affected fetuses (%) and lower row the number of affected litters (%).

8 <sup>c</sup>Statistical analysis for fetal data including litter effects performed using a Rao-Scott modification to the Cochran-Armitage test where the litter was the random effect for both trend and pairwise analyses.

9 <sup>d</sup>Historical control incidence: fetuses – 0/1,385; litters – 0/97.

10 <sup>e</sup>Historical control incidence: fetuses – 4/1,385 (0.29%), range 0.00% to 0.81%; litters – 4/97 (4.12%), range 0.00% to 16.67%.

11 <sup>f</sup>Historical control incidence: fetuses – 60/1,385 (4.33%), range 1.28% to 7.85%; litters – 28/97 (28.87%), range 12.50% to 43.18%.

12 <sup>g</sup>Historical control incidence: fetuses – 151/1,385 (10.90%), range 4.83% to 15.36%; litters – 55/97 (56.70%), range 43.75% to 68.18%.

13 <sup>h</sup>Historical control incidence: fetuses – 1/1,385 (0.07%), range 0.00% to 0.17%; litters – 1/97 (1.03%), range 0.00% to 2.27%.

1 **Head**

2 There was no effect of 2H4MBP or EE exposure on the incidence of fetal head abnormalities at  
3 the exposures tested. Fetal head abnormalities were limited to a single fetus in the 3,000 ppm  
4 group that displayed anophthalmia of the right eye (Appendix E).

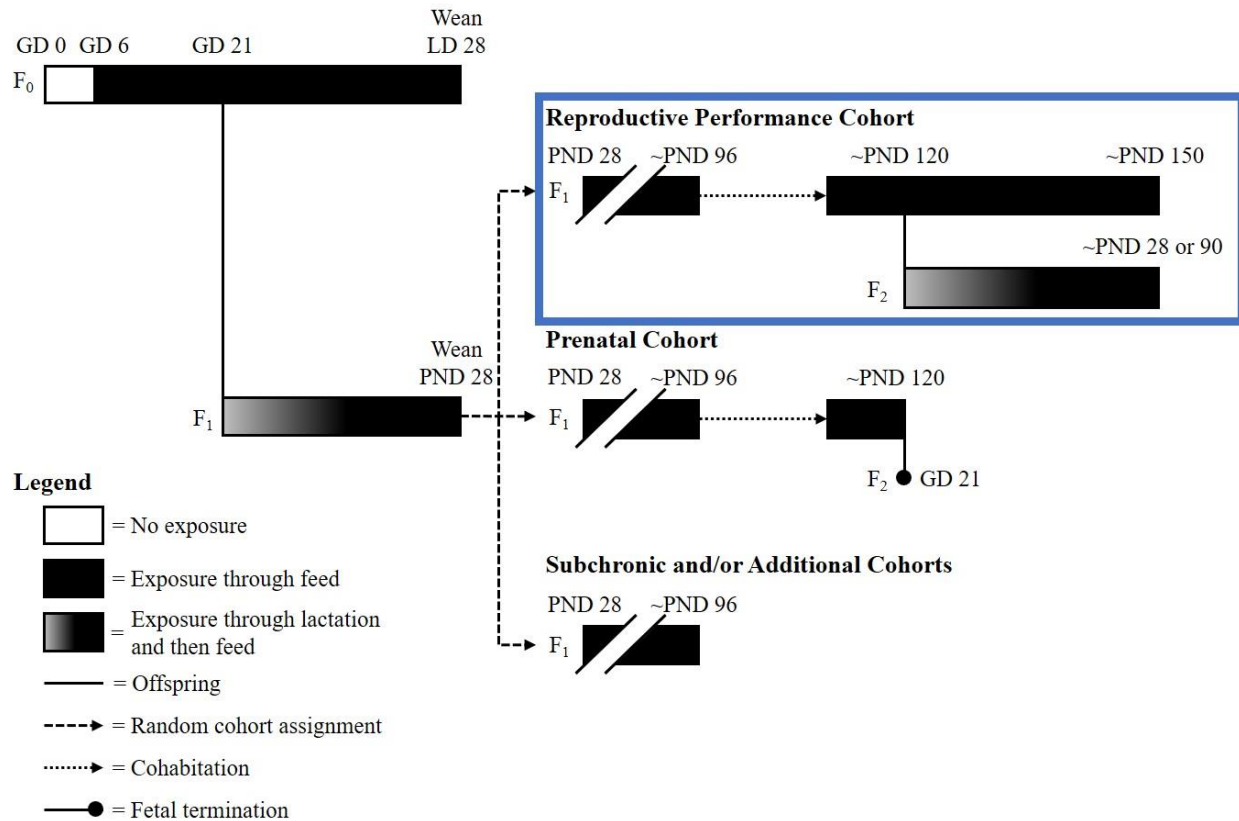

5 **Skeletal**

6 There was no effect of 2H4MBP or EE exposure on the incidence of fetal skeletal abnormalities  
7 at the exposures tested (Appendix E). Skeletal malformations in exposed groups were limited to  
8 fused sternebrae, multiple rib abnormalities, and vertebral abnormalities in a single fetus in the  
9 30,000 ppm 2H4MBP group. Full lumbar 1 ribs were observed in several fetuses in the 3,000  
10 and 10,000 ppm 2H4MBP groups. Given the low incidence and exposure response, these  
11 findings were not considered 2H4MBP-related.

12 Skeletal variations observed in 2H4MBP- and/or EE-exposed groups included incomplete  
13 ossification of the parietal skull, sternebrae extra ossification sites, misaligned sternebrae,  
14 incomplete sternebrae ossification (II, III, IV, V, VI), rudimentary rib (lumbar 1), thoracic  
15 centrum bipartite ossification, and thoracic centrum dumbbell ossification. With the exception of  
16 the lumbar 1 rudimentary rib variation, the incidences of the variations were limited to <3 fetuses  
17 per group. The incidences of the skeletal variations were not considered related to the test article  
18 because there was no exposure-related trend and/or the incidences were similar to the concurrent  
19 control group (Appendix E).

## 1 Reproductive Performance Cohort Findings

2 F<sub>1</sub> and F<sub>2</sub> rats from the reproductive performance cohort were evaluated for maternal  
 3 reproductive performance and offspring effects, respectively, as shown in Figure 23. Littering,  
 4 mean body weights, and feed consumption results from the F<sub>1</sub> rats as well as viability, clinical  
 5 observations, mean body weights, and gross pathology results from the F<sub>2</sub> rats are presented  
 6 below.

7  
 8 **Figure 23. Design of the Modified One-Generation Study – Reproductive Performance Cohort**

9 GD = gestation day; LD = lactation day; PND = postnatal day.

## 10 Reproductive Performance and Littering

11 Reproductive performance and littering parameters for the reproductive performance cohort are  
 12 presented in Table 24. Gestation length was similar among the 2H4MBP-exposed groups and the  
 13 control group. The EE group displayed a significant decrease (approximately 0.4 days) in  
 14 gestation length compared to the control group.

1 **Table 24. Summary of Reproductive Parameters of F<sub>1</sub> Female Rats in the Reproductive**  
 2 **Performance Cohort Exposed to 2-Hydroxy-4-methoxybenzophenone in Feed**

	0 ppm	3,000 ppm	10,000 ppm	30,000 ppm	EE 0.05 ppm <sup>a</sup>
No. Females Paired	41	40	40	40	30
No. Females Mated	40	37	35	35	29
No. Females Littering	35	37	33	32	28
Percent of Mated Females/Paired <sup>b,c</sup>	97.6	92.5	87.5	87.5	96.7
Percent of Littered Females/Paired <sup>b,c</sup>	85.4	92.5	82.5	80.0	93.3
Percent of Littered Females/Mated <sup>b,c</sup>	87.5	100.0	94.3	91.4	96.6
Precoital Interval (days) <sup>d,e,f</sup>	4.7 ± 0.6 (22)	4.8 ± 0.5 (20)	5.1 ± 0.7 (19)	4.2 ± 0.8 (20)	4.0 ± 0.6 (15)
Gestation Length (days) <sup>d,e,g</sup>	22.4 ± 0.1 (22)	22.5 ± 0.1 (20)	22.6 ± 0.1 (19)	22.2 ± 0.1 (20)	22.0 ± 0.1** (15)

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 \*\*Statistically significant at  $p \leq 0.01$ .

5 EE = ethinyl estradiol.

6 <sup>a</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

7 <sup>b</sup>Statistical analysis performed using the Rao-Scott Cochran-Armitage test for both trend and pairwise comparisons to adjust for  
 8 litter effects (unless otherwise noted).

9 <sup>c</sup>Animals removed from the study between mating and littering were excluded from calculations of percent littered females.

10 <sup>d</sup>Statistical analysis performed using a bootstrapped Jonckheere test for trend, and a Datta-Satten modified Wilcoxon test with  
 11 Hommel adjustment for pairwise comparisons.

12 <sup>e</sup>Data are displayed as mean ± standard error (n).

13 <sup>f</sup>Precoital interval calculated for sperm-positive females.

14 <sup>g</sup>Gestation length calculated for sperm-positive females that delivered a litter.

### 15 **Lactation Body Weights and Feed Consumption**

16 Consistent with their pre-mating and gestation weights, F<sub>1</sub> female mean body weights during  
 17 lactation were significantly decreased in the 10,000 and 30,000 ppm 2H4MBP and 0.05 ppm EE  
 18 groups relative to the control group (Table 25; Figure 24). On LDs 1 and 28, female mean body  
 19 weights of the 10,000 and 30,000 ppm 2H4MBP and 0.05 ppm EE groups were significantly  
 20 decreased by 5%–7%, 18%–20%, and 19%–21%, respectively, compared to the control group.  
 21 Body weight gain between LD 1 and LD 28 in the 10,000 and 30,000 ppm 2H4MBP and  
 22 0.05 ppm EE groups was higher relative to the control group. In general, feed consumption  
 23 values during lactation in the groups exposed to 2H4MBP or EE were similar to the control  
 24 group (Table 25). 2H4MBP intake during lactation in the 3,000, 10,000, and 30,000 ppm  
 25 2H4MBP groups, based on feed consumption and dietary concentrations for the LD 1–13  
 26 interval, was approximately 426, 1,621, and 5,944 mg/kg/day, respectively (Table 25). EE intake  
 27 during the postweaning period was approximately 0.009 mg/kg/day.

2 **Figure 24. Lactation Growth Curves for F<sub>1</sub> Female Rats in the Reproductive Performance Cohort**  
3 **Exposed to 2-Hydroxy-4-methoxybenzophenone in Feed**

4 EE = ethinyl estradiol. Information for statistical significance in F<sub>1</sub> female rat weights is provided in Table 25.

## 5 **F<sub>2</sub> Viability and Clinical Observations**

6 Clinical observations noted in individual pups in all groups, including the control group, were  
7 typically indicative of an individual pup not thriving (e.g., cold to the touch, no milk in the  
8 stomach). Exposure-related reductions in mean total and live litter size were observed in the  
9 2H4MBP- and EE-exposed groups. Dams in the 10,000 and 30,000 ppm 2H4MBP groups had  
10 lower total and live litter size than the control group on PND 0 (by ~1 pup/litter). Total and live  
11 litter size in the EE-exposed group were significantly decreased (by ~2 pups/litter) on PND 0  
12 than in the control group (Table 26). Although the reductions in mean live litter size in the  
13 2H4MBP-exposed groups did not achieve statistical significance compared to the control group  
14 after PND 0, the findings were consistent with the reductions in the mean number of live  
15 fetuses/pregnant females that were observed in the prenatal cohort (Table 22).

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 Statistical significance for the vehicle control group indicates a significant trend test.

5 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

6 EE = ethinyl estradiol.

7 <sup>a</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

8 <sup>b</sup>n = the number of pups examined (number of F<sub>1</sub> litters).

9 <sup>c</sup>Data are displayed as the mean of litter values ± standard error of litter values (n = number of litters produced by F<sub>0</sub> dams); n is  
 10 dependent on the number of litters produced by the F<sub>0</sub> generation in which up to two nonindependent F<sub>1</sub> offspring/sex/litter were  
 11 selected to produce F<sub>2</sub> pups through nonsibling mating.

12 <sup>d</sup>Statistical analysis performed using a bootstrapped Jonckheere test for trend, and a Datta-Satten modified Wilcoxon test with  
 13 Hommel adjustment for pairwise comparisons.

**1 F<sub>2</sub> Body Weights****2 Male Pups**

3 Male pups exposed to 30,000 ppm 2H4MBP displayed lower mean body weights (litter means)  
4 over time compared to the control group (Table 27; Figure 25; Appendix E). On PND 21, male  
5 pup mean body weights per litter of the 30,000 ppm group were lower by approximately 8% and  
6 by PND 28 they were significantly decreased 15% relative to the control group. A significant  
7 decrease in pup mean body weight was first observed in male offspring on PND 25. These  
8 effects are consistent with what was observed in the F<sub>1</sub> generation, but the magnitude of change  
9 with exposure concentration is not as severe. EE exposure had no adverse effect on male pup  
10 mean body weights.

**11 Female Pups**

12 Female pups exposed to 30,000 ppm 2H4MBP also displayed lower mean body weights (litter  
13 means) relative to the control group (Table 27; Figure 26; Appendix E). On PND 21  
14 and PND 28, female pup mean body weights per litter of the 30,000 ppm group were  
15 significantly decreased by approximately 12% and 21% relative to the control group,  
16 respectively. A significant decrease in pup mean body weight was first observed in female  
17 offspring on PND 16. These effects are consistent with what was observed in the F<sub>1</sub> generation,  
18 but the magnitude of reduction with exposure concentration is not as severe. There was no  
19 adverse effect of EE exposure on female pup mean body weights.

## 1 Prenatal and Reproductive Performance Cohorts: Necropsies

### 2 F<sub>1</sub> Male Necropsies

3 F<sub>1</sub> males in the reproductive performance cohort were euthanized following the mating period at  
4 153–155 days of age. The F<sub>1</sub> males in the prenatal cohort were euthanized following completion  
5 of pairing at 111–113 days of age.

6 Male rats exposed to 30,000 ppm 2H4MBP displayed a higher incidence of discolored (pale or  
7 dark) or enlarged kidneys and discolored (brown) urinary bladders (Table 28). Necropsy mean  
8 body weights of rats exposed to 30,000 ppm 2H4MBP or 0.05 ppm EE in both cohorts were  
9 significantly decreased by 14% and 15%–20%, respectively, compared to control animals  
10 (Table 29). Rats in both cohorts from all 2H4MBP-exposed groups displayed higher left and  
11 right absolute and relative kidney weights (Table 29). Absolute kidney weights were 5%–12%,  
12 10%–14%, and 13%–22% higher and relative weights were 7%–10%, 15%–16%, and  
13 30%–42% higher than those of control animals in the 3,000, 10,000, and 30,000 ppm groups,  
14 respectively. Gross findings in the kidney and bladder correlated with histopathological changes  
15 consistent with a retrograde nephropathy. One male rat in the 30,000 ppm 2H4MBP group in the  
16 reproductive performance cohort exhibited a diaphragmatic hernia. These hernias were also  
17 observed in F<sub>1</sub> females and in the F<sub>2</sub> generation. One male in the 30,000 ppm 2H4MBP group  
18 displayed hypospadias and another displayed bilateral smaller testes (Appendix E).

19 Male rats in all 2H4MBP-exposed groups in both cohorts displayed higher absolute and relative  
20 liver weights compared to the control animals (Table 29). Absolute liver weights of males  
21 exposed to 3,000 ppm 2H4MBP in the reproductive performance and prenatal cohorts were  
22 higher by 6% and 11%, respectively, relative to control animals. Absolute liver weights of males  
23 in both cohorts exposed to 10,000 and 30,000 ppm were significantly increased 14%–20%  
24 relative to control animals. Relative liver weights of the 3,000, 10,000, and 30,000 ppm  
25 2H4MBP groups in both cohorts were significantly increased approximately 7%–9%,  
26 20%–23%, and 32%–34%, respectively, relative to the control group. The reproductive  
27 performance and prenatal cohorts displayed generally similar responses.

28 Rats in both cohorts exposed to 30,000 ppm 2H4MBP displayed slightly lower right and left  
29 absolute testis weights (approximately 4%–6%) (Table 29). Rats exposed to 30,000 ppm in the  
30 reproductive performance cohort exhibited a slight but significant decreased (5%–6%) right and  
31 left absolute epididymis weights. Absolute ventral prostate gland weights of the 30,000 ppm  
32 2H4MBP groups were significantly decreased 19% and 10% relative to control animals in the  
33 reproductive performance and prenatal cohorts, respectively. This difference in cohort response  
34 might be due to duration of exposure being longer in the reproductive performance cohort. No  
35 2H4MBP-related histopathological effects in the testis or epididymis were found. No exposure-  
36 related changes in sperm motility, sperm concentration, or testicular sperm head concentration  
37 were found (Appendix E). Rats in the 30,000 ppm 2H4MBP group in both cohorts displayed  
38 significantly decreased absolute levator ani/bulbocavernosus (LABC) muscle weights  
39 (10%–12%); however, when adjusted for body weight, this difference was negligible (Table 29).  
40 No gross pathological findings in the males exposed to 0.05 ppm EE were considered to be  
41 related to exposure. In general, male rats exposed to EE displayed lower absolute weights of the  
42 testes, epididymides, prostate gland, kidney, liver, seminal vesicles with coagulating glands, and

1 LABC. These observations are likely the result of animals weighing 15%–20% less than control  
2 animals.

1 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group. Statistical significance for the vehicle control group  
2 indicates a significant trend test.

3 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

4 EE = ethinyl estradiol; RPC = reproductive performance cohort; PC = prenatal cohort.

5 <sup>a</sup>Data are displayed as mean ± standard error of the litter means.

6 <sup>b</sup>Statistical analysis for the RPC performed using the Jonckheere (trend) and Williams or Dunnett (pairwise) tests. Statistical analysis for the PC performed using mixed models  
7 with a random effect for litter and a Dunnett-Hsu adjustment for multiple pairwise comparisons.

8 <sup>c</sup>The EE group was not included in any trend analysis, it was included in the pairwise analysis to the vehicle control group.

9 <sup>d</sup>Relative organ weights (organ-weight-to-body-weight ratios) are given as mg organ weight/g body weight.

10 <sup>e</sup>For the PC, n = 22, 19, 20, and 16 litters for the 0, 3,000, 10,000, and 30,000 ppm groups, respectively. For the RPC, n = 19 litters for the 3,000 ppm group.

## 1 **F<sub>1</sub> Female Necropsies**

2 F<sub>1</sub> females (and F<sub>2</sub> offspring) in the reproductive performance cohort were euthanized and  
3 necropsied on PND 28, when the F<sub>1</sub> females were between 127 and 168 days of age. F<sub>1</sub> females  
4 in the prenatal cohort were between 109 and 132 days of age at the time of necropsy and the  
5 collection of organ weight data.

6 There were no gross observations in the prenatal cohort attributed to 2H4MBP exposure.  
7 Females in the reproductive performance cohort exposed to 30,000 ppm 2H4MBP displayed a  
8 higher individual and litter incidence of abnormal kidney findings (dilation, discoloration)  
9 (Table 30). These findings were also observed at a low incidence in the 3,000 ppm group and are  
10 consistent with what was observed in the F<sub>1</sub> males. This difference in response between the two  
11 cohorts might have been the result of duration of exposure and is consistent with what was  
12 observed in the F<sub>1</sub> males.

13 The reproductive performance and prenatal cohorts exposed to 10,000 or 30,000 ppm 2H4MBP  
14 displayed terminal/adjusted body weights that were significantly decreased 5%–8% and  
15 18%–19%, respectively, compared to the control females (Table 31). Females in all 2H4MBP-  
16 exposed groups from both cohorts displayed significantly increased relative liver weights (10%–  
17 14%, 17%–32%, and 28%–53% in the 3,000, 10,000, and 30,000 ppm groups, respectively)  
18 compared to the control females (Table 31). Rats in the reproductive performance cohort  
19 exposed to 3,000, 10,000, and 30,000 ppm 2H4MBP displayed higher (approximately 5%–7%,  
20 11%, and 24%–30%, respectively) relative right and left kidney weights compared to the control  
21 group. Absolute kidney weights were significantly decreased (12%–14%) compared to the  
22 control group in females in the reproductive performance cohort exposed to 0.05 ppm EE.  
23 Relative liver weights were significantly increased in the 0.05 ppm EE groups in both cohorts  
24 compared to the control groups, likely because necropsy body weights were lower than those of  
25 the control group.

26 Females exposed to 10,000 or 30,000 ppm 2H4MBP in both cohorts displayed lower absolute  
27 right and left ovarian weights (Table 31). Females in the reproductive performance cohort  
28 exposed to 30,000 ppm 2H4MBP displayed significantly decreased absolute adrenal gland  
29 weight compared to the control group. Both cohorts of the EE groups had lower absolute ovarian  
30 and adrenal cortical weights.

2 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group. Statistical significance for the vehicle control group  
3 indicates a significant trend test.

4 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

5 EE = ethinyl estradiol; RPC = reproductive performance cohort; PC = prenatal cohort.

6 <sup>a</sup>Data displayed as mean ± standard error of the litter means.

7 <sup>b</sup>Statistical analysis for the RPC performed using the Jonckheere (trend) and Williams or Dunnett (pairwise) tests. Statistical analysis for the PC performed using mixed models  
8 with a random effect for litter and a Dunnett-Hsu adjustment for multiple pairwise comparisons.

9 <sup>c</sup>The EE group was not included in any trend analysis; it was included in the pairwise analysis to the vehicle control group.

10 <sup>d</sup>The terminal body weight for the prenatal females is the final body weight minus the gravid uterine weight.

11 <sup>e</sup>Relative organ weights (organ-weight-to-body-weight ratios) are given as mg organ weight/g body weight.

12 <sup>f</sup>n = 19 for the 10,000 ppm group in the RPC. The decrease is due to one female's value being excluded because it was an outlier.

## 1 **F<sub>2</sub> Necropsy**

2 Pups were euthanized on PND 28; gross pathology findings are reported in Appendix E. One  
3 male each in the 3,000 and 30,000 ppm 2H4MBP groups exhibited bilateral undescended testes.  
4 Three males each in the 3,000 and 10,000 ppm 2H4MBP groups exhibited unilateral  
5 undescended testes. Several females in the 30,000 ppm 2H4MBP group displayed dilated,  
6 discolored, or enlarged kidneys consistent with what was observed in adults. Diaphragmatic  
7 hernias were observed in three males in the 30,000 ppm 2H4MBP group and in one male in the  
8 EE group (Appendix E). Diaphragmatic hernias were also observed in 2H4MBP- or EE-exposed  
9 F<sub>1</sub> rats in the reproductive performance cohort (Appendix E). The collective EE group had two  
10 males with diaphragmatic hernias. No hernias were observed in control animals or in the  
11 F<sub>0</sub> females (Appendix E). These hernias consist of a small protrusion of the liver through the  
12 diaphragm and are sometimes recorded grossly as diaphragmatic hernias and sometimes as  
13 hepatodiaphragmatic hernias.

## 14 **Pathology**

15 This section describes the statistically significant or biologically noteworthy changes in the  
16 incidences of nonneoplastic lesions. Summaries of the incidences of nonneoplastic lesions  
17 mentioned in this section are presented as supplemental data in Appendix E.

18 *Kidney:* The kidney was the primary target of 2H4MBP exposure (Table 32; Appendix E). In the  
19 F<sub>1</sub> reproductive performance cohort, the incidences of renal tubule epithelial regeneration were  
20 significantly increased in the 30,000 ppm males and females relative to their respective control  
21 groups; a higher incidence of this lesion was also noted in the 10,000 ppm females. When  
22 compared to control animals, both male and female rats exposed to 30,000 ppm had significantly  
23 increased incidences of interstitial chronic active inflammation, renal tubule concretions, renal  
24 tubule dilation, urothelial hyperplasia, and urothelial ulcers. In the F<sub>1</sub> reproductive performance  
25 cohort, pelvic concretion and papillary necrosis was significantly increased compared to control  
26 animals in the 30,000 ppm males, and there was a positive trend for pelvic concretion and  
27 papillary necrosis in the females. F<sub>1</sub> females in the reproductive performance cohort also had  
28 significantly increased incidences of renal tubule epithelial degeneration (30,000 ppm), chronic  
29 progressive nephropathy (3,000 and 10,000 ppm), and mineralization (3,000 and 10,000 ppm)  
30 compared to control animals, and there was a positive trend for pelvic dilation. Renal lesions  
31 were also observed in the F<sub>0</sub> and other cohorts (see below).

32 Interstitial chronic active inflammation was characterized by a mixture of inflammatory cell  
33 types, including neutrophils, lymphocytes, and macrophages, with some fibrosis. This lesion was  
34 distinct from the interstitial infiltrates of mononuclear cells that accompanies chronic progressive  
35 nephropathy. When the renal papilla was necrotic, it was frequently no longer visible in the  
36 section of tissue, with just eosinophilic amorphous material present where the tip of the papilla  
37 should be. When the necrotic papilla was still present in the section, it was characterized by a  
38 pale, washed out, eosinophilic color and lack of cellular detail. Renal tubule dilation was the  
39 most frequently observed change in the kidneys of male and female rats and was frequently  
40 accompanied by intratubular accumulations of round or angular pale-brown to red-brown  
41 material, often with a laminated appearance. These renal tubular concretions were similar to the  
42 pelvic concretions. Other dilated renal tubules contained proteinaceous casts, characterized by  
43 homogenous, bright eosinophilic material, or cell debris. Renal tubule dilation was generally a

1 focal change, most often involving the poles of the kidney, which affected the entire length of the  
2 nephron. The epithelium lining the dilated tubules was flattened and frequently showed evidence  
3 of degeneration (females) or regeneration (males and females).

4 Renal tubule epithelial degeneration was characterized by the absence of epithelial cells or the  
5 presence of individual necrotic epithelial cells, whereas renal tubule epithelial regeneration was  
6 characterized by plump epithelial cells with basophilic cytoplasm that projected into the tubular  
7 lumen. Regeneration most likely occurred after degeneration, and the lack of observed  
8 degeneration in the males might imply a quicker onset or a more severe course of renal tubular  
9 epithelial degeneration in male rats relative to female rats. Urothelial hyperplasia consisted of an  
10 increased number of cell layers of the epithelium lining the renal pelvis and occurred as either a  
11 focal (males) or diffuse (males and females) change. The severity of the lesion was based on the  
12 thickness of the hyperplasia as well as on the amount of pelvis involved, with focal lesions being  
13 less severe than those involving the entire renal pelvis (diffuse). Urothelial hyperplasia was  
14 usually of minimal to mild severity, but in one female rat, moderate urothelial hyperplasia was  
15 accompanied by squamous metaplasia of the urothelium. Ulceration of the urothelium was  
16 characterized by a focal area devoid of epithelium. Roughly half of the animals with ulcers of the  
17 urothelium also had urothelial hyperplasia. One male rat had necrosis of the urothelium; focal  
18 necrosis typically develops into an ulcer as the necrotic epithelium is sloughed off. Pelvic  
19 dilation was characterized by an increased space between the renal papilla and the renal pelvis.  
20 In most cases, papillary necrosis was evidenced by the absence of the tip of the papilla and  
21 accumulations of pale, eosinophilic material where the tip of the papilla should be. Occasionally,  
22 the tip of the papilla was still in place but was pale and lacked nuclear detail. Most occurrences  
23 of chronic progressive nephropathy were of minimal or mild severity; minimal nephropathy  
24 consisted of basophilic tubules with a thickened basement membrane, whereas mild cases of  
25 nephropathy typically also had tubular proteinaceous casts and mixed mononuclear cell  
26 inflammation within the interstitium. Mineralization was characterized by small focal deposits of  
27 deeply basophilic granular material, typically along the corticomedullary junction; evidence of  
28 minimal secondary renal tubule necrosis was occasionally associated with mineral deposition but  
29 not recorded separately.

30 The various renal lesions associated with exposure to 30,000 ppm 2H4MBP were consistent with  
31 an obstructive nephropathy. Obstructive nephropathy occurs when something restricts the  
32 outflow of urine, such as crystals, with subsequent inflammation or a lower urinary tract  
33 blockage. Retrograde nephropathy, which is a form of obstructive nephropathy, is due to urine  
34 backflow into the kidney, causing tubule dilation that ascends from the papilla to the cortex.<sup>96; 97</sup>

35 F<sub>0</sub> females, F<sub>1</sub> males in the prenatal cohort, and F<sub>2</sub> males and females were also necropsied;  
36 however, only lesions that were grossly visible at the time of necropsy were examined  
37 histologically. Only one F<sub>1</sub> female from the prenatal cohort, a 3,000 ppm 2H4MBP group  
38 animal, was examined histologically, and there were no gross or histological lesions of the  
39 kidney. In the F<sub>0</sub> females, 0, 0, 1, and 7 animals from the 0, 3,000, 10,000, and 30,000 ppm  
40 2H4MBP groups had gross lesions, and 0, 0, 0, and 3 had gross lesions of the kidneys,  
41 respectively. The three F<sub>0</sub> females in the 30,000 ppm group had pale kidneys observed at  
42 necropsy; this observation was associated histologically with various kidney lesions, including  
43 renal tubule dilation, renal tubule epithelial regeneration, interstitial chronic active inflammation,  
44 papillary necrosis, and urothelial hyperplasia. In F<sub>1</sub> males from the prenatal cohort, 2, 2, 2, and  
45 15 animals from the 0, 3,000, 10,000, and 30,000 ppm 2H4MBP groups had gross lesions, of

1 which 0, 0, 2, and 13 animals had gross lesions of the kidneys, respectively. Gross lesions  
2 included enlarged and discolored kidneys in the 30,000 ppm group and dilated pelvis in the  
3 10,000 ppm group. Histologically, the kidneys from the 30,000 ppm group had papillary necrosis  
4 and pelvic concretions, renal tubule dilation and concretions, renal tubule epithelial regeneration,  
5 and hyperplasia and ulceration of the urothelium; the kidneys from females in the 10,000 ppm  
6 group had pelvic dilation.

7 In the F<sub>2</sub> males, 2, 5, 6, and 6 animals from the respective 0, 3,000, 10,000, and 30,000 ppm  
8 2H4MBP groups had gross lesions, of which 1, 0, 3, and 0 had gross lesions of the kidneys.  
9 Gross lesions included discoloration and pelvic dilation, which were seen histologically as  
10 congestion and pelvic dilation. In the F<sub>2</sub> females, 2, 1, 0, and 8 animals had gross lesions from  
11 the respective 0, 3,000, 10,000, and 30,000 ppm 2H4MBP groups, of which 1, 0, 0, and 7 had  
12 gross lesions of the kidneys. Histological findings associated with these gross findings included  
13 renal tubule and pelvic dilation (Appendix E).

3 Statistical significance for an exposure group indicates a significant pairwise test compared to the vehicle control group.

4 Statistical significance for the vehicle control group indicates a significant trend test.

5 \*Statistically significant at  $p \leq 0.05$ ; \*\* $p \leq 0.01$ .

6 EE = ethinyl estradiol.

7 <sup>a</sup>Statistical analysis performed using the Cochran-Armitage test with a Poly-3 adjustment for age and a Rao-Scott modification  
 8 for the random effect due to litter.

9 <sup>b</sup>Number of animals (number of litters) with tissue examined microscopically.

10 <sup>c</sup>Number of animals (number of litters) with lesion.

11 <sup>d</sup>Average severity grade of lesions in affected animals: 1 = minimal, 2 = mild, 3 = moderate, 4 = marked.

12 <sup>e</sup>Nonneoplastic lesions were not evaluated in the EE group.

1 *Urinary Bladder:* In F<sub>1</sub> males from the reproductive performance cohort exposed to 30,000 ppm  
 2 2H4MBP, there was an increase, although not significant, in the incidences of urinary bladder  
 3 concretions (Appendix E). Most of these animals had gross observations of brown discoloration  
 4 in the urinary bladder.

5 *Liver:* Hepatodiaphragmatic hernias (HDN) occurred at a low incidence in the 10,000 and  
 6 30,000 ppm males and females and in the 3,000 ppm females in the F<sub>1</sub> reproductive performance  
 7 cohort (0, 0, 1, 1 for the 0, 3,000, 10,000, and 30,000 ppm males, respectively; 0, 2, 1, 4 for the  
 8 0, 3,000, 10,000, and 30,000 ppm females, respectively). Although none of the incidences was  
 9 statistically different from control animals, no occurrences of HDN were observed in either the  
 10 male or female control groups (Table 33). All but two of the HDNs (one in the 10,000 ppm  
 11 males and one in the 30,000 ppm females) correlated with gross observations of diaphragmatic  
 12 hernias at necropsy. HDNs were rounded protrusions of the liver that were histologically similar  
 13 to normal liver.

 22 for the random effect due to litter.

23 <sup>e</sup>Number of animals with tissue examined microscopically [number of litters].

24 *Preputial Gland:* There was a significant increase in the incidence of preputial gland, duct  
 25 ectasia in F<sub>1</sub> males in the reproductive performance cohort exposed to 30,000 ppm 2H4MBP  
 26 (Appendix E). This lesion consists of a dilation of the ducts of the preputial gland and is a  
 27 common background change seen in rats, especially as they age. In its most severe form, ectatic  
 28 ducts become cystic or even rupture, inciting a marked inflammatory reaction. The average  
 29 severities of these lesions were between minimal and mild in the control group and exposed  
 30 groups. The biological importance of this lesion is unknown.

## 1 Discussion

2 The objective of the present study was to characterize the potential for  
3 2-hydroxy-4-methoxybenzophenone (2H4MBP), a common component of sunscreen and  
4 personal care products, to adversely affect any phase of rat development, maturation, and ability  
5 to reproduce. Mechanistic screening studies have shown that 2H4MBP and its metabolites are  
6 capable of activating the estrogen receptor and antagonizing the androgen receptor to varying  
7 degrees.<sup>98; 99</sup> In this study, Sprague Dawley (Hsd:Sprague Dawley<sup>®</sup> SD<sup>®</sup>) rats were exposed to  
8 2H4MBP in 5K96 feed, using the National Toxicology Program (NTP) modified one-generation  
9 (MOG) study design. As disposition is similar following oral and dermal exposure, 2H4MBP  
10 exposure via the diet was selected for this study, rather than topical application, to sustain  
11 internal exposure; if applied topically, internal dose would be influenced by intra- and  
12 interanimal grooming behavior. To minimize the potential endocrine activity of phytoestrogens  
13 that are often present in rodent diets, 5K96 feed was used because it provides a diet low in  
14 phytoestrogens. This report complements ICH<sup>c</sup> S5r2 guideline studies (fertility and early  
15 embryonic development, embryo-fetal development, and pre- and postnatal developmental  
16 studies in rats) on 2H4MBP<sup>53</sup> conducted by the U.S. Food and Drug Administration's National  
17 Center for Toxicological Research (NCTR), an interagency NTP partner, and allows for the  
18 comparison of study designs and outcomes.

19 Exposure concentration selection was informed by a dose range-finding study that demonstrated  
20 that 25,000 ppm was well tolerated in pregnant rats and did not affect parturition, litter size, or  
21 pup viability. In that study, pup body weights of the 25,000 ppm group were significantly  
22 decreased compared to the control group, suggesting potential growth retardation; this response  
23 was severe at the 50,000 ppm exposure concentration and viable litter size was also affected.  
24 Therefore, 30,000 ppm was selected as the highest exposure concentration for the MOG study.  
25 The exposure concentrations of 3,000 and 10,000 ppm were selected to aid in identifying  
26 potential exposure concentration-response relationships. This spacing would ideally avoid  
27 significant overlap of the respective mg 2H4MBP/kg body weight (mg/kg) exposure  
28 concentrations, recognizing that the amount of feed consumed is dependent on pregnancy state  
29 (e.g., prior to mating versus lactation), sex, and age. Because 2H4MBP has been reported to  
30 induce estrogen-like activity, a low exposure concentration (0.05 ppm) of ethinyl estradiol (EE),  
31 a synthetic form of estrogen, was included as a positive control group. NTP studies have shown  
32 that comparing plasma concentrations of 2H4MBP in rats following feed exposure of 3,000–  
33 30,000 ppm to plasma concentrations in humans following repeated dermal application of  
34 20 g/m<sup>2</sup> revealed rat-to-human dose multiples of 0.1 to 4.<sup>19</sup> Collectively, these data demonstrate  
35 similar external (5- to 57-fold) and internal (0.1- to 4-fold) exposure of 2H4MBP in rats and  
36 humans.

37 Exposure of F<sub>0</sub> females to 2H4MBP or EE via the diet began on gestation day (GD) 6  
38 (implantation). F<sub>1</sub> offspring were exposed to 2H4MBP or EE at the same exposure concentration  
39 as their respective dams. Upon weaning, F<sub>1</sub> offspring in each group were randomly assigned to  
40 one of three cohorts: (1) reproductive performance cohort (2/sex/litter), (2) prenatal cohort

---

<sup>c</sup>ICH = International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use.

1 (1/sex/litter), and (3) biological sampling cohort (1/sex/litter). Upon sexual maturity, nonsibling  
2 F<sub>1</sub> rats allocated to the prenatal and reproductive performance cohorts were paired for mating to  
3 evaluate reproductive performance and F<sub>2</sub> prenatal and postnatal development. The likelihood of  
4 identifying potential 2H4MBP-induced adverse effects (similarity and magnitude thereof) at any  
5 phase of growth or development was increased by examining related endpoints in multiple pups  
6 within a litter during both preweaning and postweaning periods.

7 The concentrations of free (unconjugated compounds) and total (free and all conjugated forms)  
8 2H4MBP, 2,4-dihydroxybenzophenone (DHB), 2,3,4-trihydroxybenzophenone (THB), and  
9 2,5-dihydroxy-4-methoxybenzophenone (D2H4MBP) were quantified in plasma from the  
10 biological sampling cohort at postnatal days (PNDs) 28 and 56.<sup>64</sup> Free plasma 2H4MBP and  
11 DHB concentrations were similar to each other and increased with increasing exposure  
12 concentration, with no age or sex differences except in the 10,000 ppm group, as concentrations  
13 of both analytes were significantly increased in PND 56 animals relative to PND 28 animals.  
14 Free D2H4MBP and THB were not detected in these animals. The concentrations of total  
15 2H4MBP and DHB were higher (approximately 100- to 300-fold) than the free 2H4MBP and  
16 DHB concentrations, demonstrating extensive conjugation of 2H4MBP and its metabolites. The  
17 rank order of the total concentrations was 2H4MBP  $\approx$  DHB > D2H4MBP  $\gg$  THB. Free and  
18 total analyte plasma concentrations were not sex-dependent in either PND 28 or PND 56 pup  
19 plasma.

20 In the current MOG study, 2H4MBP exposure was associated with lower F<sub>1</sub> and F<sub>2</sub> mean body  
21 weights (8%–24%). Lower preweaning F<sub>1</sub> pup mean body weights have also been observed in  
22 CD-1 mice exposed to 2H4MBP.<sup>41</sup> The lower F<sub>1</sub> body weights observed postweaning to sexual  
23 maturity were not associated with lower feed consumption. Pregnant F<sub>0</sub> females and females in  
24 both F<sub>1</sub> cohorts exposed to 2H4MBP also did not display decreases in gestational or lactational  
25 feed consumption. Collectively, this suggests that 2H4MBP could have altered utilization of the  
26 consumed diet (and, thus, affected growth) and could have reduced or delayed preweaning  
27 growth. The observed lower mean body weights of the 2H4MBP groups, in the absence of  
28 effects on feed consumption, is consistent with findings reported in Fischer 344 (F344)/N rats  
29 administered 25,000 ppm 2H4MBP.<sup>40</sup>

30 2H4MBP did not result in any significant effects on mating, pregnancy, or littering indices, nor  
31 did it result in adverse histopathological findings in the testis or changes in sperm parameters at  
32 concentrations up to 30,000 ppm. These observations contrast with those reported in the NTP  
33 Reproductive Assessment by Continuous Breeding study<sup>41</sup> in CD-1 mice, in which 2H4MBP  
34 was associated with smaller litter sizes and decreases in pup viability. In a previous study,  
35 50,000 ppm was associated with lower sperm density in both F344/N rats and mice. No effects  
36 on sperm parameters were apparent at the next lower exposure concentration (12,500 ppm) in  
37 rats, however, percent of sperm cell abnormalities were significantly increased in mice at this  
38 exposure concentration.<sup>40</sup> These findings were collectively attributed to stress-induced toxicity,  
39 potentially by affecting metabolism or digestive processes, as evidenced by lower mean body  
40 weights. Chronic stress is known to affect rat spermatogenesis.<sup>100; 101</sup> The absence of similarly  
41 robust effects on sperm parameters and reproductive performance in the current study might  
42 reflect strain and stock differences. Alternatively, it is possible that if higher 2H4MBP exposure  
43 concentrations could have been used in this study, a similar magnitude of response to that  
44 observed in the CD-1 mouse and F344/N rat in previous studies may have been observed, either  
45 as a stress-related response or as a more direct effect from 2H4MBP exposure.

1 Examining data across cohorts in the 30,000 ppm group, mean numbers of corpora lutea and  
2 F<sub>2</sub> implants on GD 21 were significantly decreased (3.7 and 2.7, respectively) relative to the  
3 control group, and the mean number of live fetuses was also lower (1.7). Mean live F<sub>2</sub> litter size  
4 on PND 0 was significantly decreased (1.5 pups) in the reproductive performance cohort, and  
5 F<sub>1</sub> live litter size on PND 0 was also slightly lower (<1 pup). These observations suggest that  
6 2H4MBP exposure might have affected litter size, although the magnitude of this effect was  
7 small. The slightly smaller litter size might have been due to a direct effect (the decrease of the  
8 number of ova ovulated, as evidenced by the lower number of corpora lutea enumerated in the  
9 prenatal cohort) or an indirect effect of a stress-induced response (reflected in the lower mean  
10 body weights). 2H4MBP, administered at 50,000 ppm in the diet from GD 6 through PND 23,  
11 has been shown to delay follicular development, but this was not observed at 25,000 ppm.<sup>18</sup>  
12 2H4MBP has also been shown to affect early follicular assembly in rat ovary cultures.<sup>102</sup> Thus,  
13 the observed decrease in corpora lutea is consistent with alterations in follicular development.<sup>18</sup>  
14 No subsequent 2H4MBP-related effects on live litter size were observed. Collectively, given the  
15 minimal apparent response that may or may not be a direct effect of 2H4MBP, this was  
16 considered equivocal evidence of an adverse effect on reproductive performance.

17 EE exposure did not affect F<sub>1</sub> live litter size on PND 0; however, mean live F<sub>2</sub> litter size on  
18 PND 0 in the reproductive performance cohort and the mean number of live F<sub>2</sub> fetuses per litter  
19 on GD 21 in the prenatal cohort were both significantly decreased (approximately 2–3 pups per  
20 litter) relative to the control group. Fewer corpora lutea and total F<sub>2</sub> implants were observed in  
21 the EE prenatal cohort. Rat follicular development has been shown to be affected by EE  
22 (200 µg/kg) when exposed on PND 0 and examined on PND 21.<sup>103</sup> F<sub>2</sub> live litter size on PND 0  
23 through PND 4 in the EE F<sub>2</sub> reproductive performance cohort was significantly decreased  
24 relative to the control group (approximately 2 pups per litter) in part because 3 of the 18 EE  
25 litters had 0 pups. After litter standardization on PND 4, survival in the EE group appeared  
26 higher than in the control group, but this was likely the result of several control litters that  
27 exhibited excessive pup loss. In a previously conducted multigenerational study, EE exposure at  
28 0.05 ppm was not reported to significantly decrease (or increase) the number of live pups born.<sup>93</sup>  
29 Upon inspection of the NCTR study data, however, there is an apparent minimal nonsignificant  
30 decrease in mean live born (approximately 1 pup per litter) that is consistent with what was  
31 observed in the EE group in the current study.<sup>93</sup> A similar decrease in number of implants was  
32 observed in the NCTR Segment 1 study.<sup>104</sup>

33 Progressively lower relative preweaning F<sub>1</sub> body weights were observed in males and females  
34 exposed to 30,000 ppm 2H4MBP. On PND 4, both males and females displayed significantly  
35 decreased mean body weights of approximately 12%–14%, relative to the control group, and by  
36 PND 28, body weights of both males and females were significantly decreased by approximately  
37 24%. In contrast, F<sub>2</sub> males and females did not exceed a 10% lower relative body weight until  
38 PND 25 and PND 28, respectively. The reason for this difference in F<sub>1</sub> versus F<sub>2</sub> generational  
39 response is unclear, but it could be related to increased 2H4MBP metabolism in the F<sub>1</sub> dams  
40 resulting from sustained 2H4MBP exposure. The no-observed-effect level (NOEL) for  
41 2H4MBP-related effects on body weight is 3,000 ppm based on lower body weights in both  
42 sexes in both generations. The considerable effects on body weights associated with exposure to  
43 2H4MBP were considered some evidence of developmental toxicity.

44 2H4MBP did not accelerate vaginal opening (VO), as would be expected if it displayed  
45 estrogenic activity, consistent with the expected robust acceleration of VO that was observed

1 with EE. The day of VO attainment was delayed in the 30,000 ppm group, and body weights on  
2 day of acquisition were similar to those of the control group. When weaning weight was used as  
3 a covariate, addressing growth retardation, the apparent delay was mitigated. A similar VO  
4 delay, concomitant with lower mean body weight, has been reported for corticosterone  
5 administered in drinking water.<sup>105</sup> Intrauterine growth retardation—after ligation of the uterine  
6 artery on GD 17 and resulting in 16% lower body weight on PND 2 and lower postnatal body  
7 weights relative to the control group—has been shown to delay VO.<sup>106</sup> Postnatal dietary  
8 restriction also has been shown to delay VO, with similar body weights relative to the control  
9 group at time of VO.<sup>107</sup> The lower PND 4 pup and postnatal mean body weights and the delay in  
10 VO observed in the current study are consistent with these findings.

11 2H4MBP exposure did not significantly alter any apical androgen-sensitive endpoints,  
12 demonstrating that it does not appear to affect androgen-mediated lengthening of anogenital  
13 distance or advancement of balanopreputial separation (BPS). 2H4MBP did not affect  
14 areola/nipple retention at the tested concentrations, indicating an absence of androgen-receptor  
15 antagonism. BPS was delayed in the 10,000 and 30,000 ppm 2H4MBP groups, as well as in the  
16 0.05 ppm EE positive control group. Similar to VO, body weights on day of acquisition were  
17 comparable to those of the control group, and, when adjusted for weaning weight, there were  
18 also no differences relative to the control group. Intrauterine growth retardation and postnatal  
19 feed restriction, resulting in lower postnatal body weights, have been shown to delay BPS.<sup>106</sup> It is  
20 plausible that, like VO, the similar weights on day of attainment observed in the current study  
21 suggest a weight or body mass requirement for the attainment of BPS.

22 Diaphragmatic hernias were observed at a low incidence in 2H4MBP-exposed animals in both  
23 the F<sub>1</sub> and F<sub>2</sub> generations but were not observed in any control animals. They were also not  
24 observed in control animals in two other MOGs (EHMC and BPAF).<sup>108; 109</sup> This finding was also  
25 observed in the male F<sub>1</sub> and F<sub>2</sub> EE groups. Diaphragmatic hernias have been shown to be  
26 induced by 2,4-dichlorophenyl-p-nitrophenyl ether, which displays some similarity to  
27 2H4MBP.<sup>110; 111</sup> The presence of gross diaphragmatic hernias correlated with histologic  
28 hepatodiaphragmatic hernias in all but two animals. Although these incidences occurred only in  
29 exposed groups, there was no exposure response and no pairwise significance, and they have  
30 been observed in control groups in other developmental and reproductive toxicity studies.  
31 Therefore, it is unclear whether the occurrence of diaphragmatic and hepatodiaphragmatic  
32 hernias were related to 2H4MBP exposure.

33 No malformations observed at adult necropsy were consistent with perturbation of normal  
34 androgen-receptor-mediated development (grossly normal prostate, seminal vesicles, and  
35 epididymis). There was, however, a single incidence of hypospadias, a lesion commonly seen  
36 when androgen action is attenuated.<sup>112; 113</sup> Given the singular incidence and the absence of  
37 corresponding changes in androgen-dependent processes, the hypospadias was likely not related  
38 to 2H4MBP exposure. In F<sub>1</sub> adult males in the reproductive performance cohort, the weights of  
39 androgen-dependent reproductive tissues (testes, epididymides, ventral prostate gland) and  
40 levator ani/bulbocavernosus muscle complex were all slightly lower in the 30,000 ppm group  
41 compared to the control group. All of those organ weight changes occurred concurrently with  
42 lower body weights, however, and are likely secondary to the apparent growth retardation.  
43 Moreover, there were no apparent 2H4MBP-related histopathological findings in the  
44 reproductive tissues, nor was the ability of males to successfully mate and induce pregnancy  
45 adversely affected in either the prenatal or reproductive performance cohorts. Sperm and

1 spermatid counts, which are androgen-sensitive endpoints, were also not affected. In totality,  
2 unlike what has been reported in cell models, 2H4MBP exposure had no apparent effect on  
3 androgen-receptor-dependent processes, nor did it affect mating or pregnancy indices.

4 2H4MBP exposure was associated with greater kidney weights and histologic lesions consistent  
5 with obstructive nephropathy, including renal tubule epithelial regeneration, renal tubule  
6 degeneration (females only), interstitial chronic active inflammation, renal tubule and pelvic  
7 concretions, renal tubule dilation, papillary necrosis, urothelial hyperplasia, and urothelial ulcers.  
8 In addition, increased chronic progressive nephropathy, pelvic dilation, and renal mineralization  
9 were present in females. These findings are consistent with renal effects previously reported  
10 following subchronic exposure<sup>40</sup> and those observed with chronic exposure.<sup>34</sup> F<sub>1</sub> males and  
11 females exposed to 2H4MBP also displayed greater liver weights. This finding is consistent with  
12 the fetal malformation finding of enlarged liver. The absolute weights of the adrenal glands were  
13 significantly decreased in the female 30,000 ppm reproductive performance cohort. Chronic  
14 stress would be expected to increase corticosterone levels and result in lower adrenal gland  
15 weights due to negative feedback; however, sustained elevated adrenocorticotrophic hormone (or  
16 equivalent) would be expected to increase both adrenal gland weight and the levels of  
17 corticosterone.<sup>114</sup> The NOEL for adult general toxicity necropsy findings is 3,000 ppm based on  
18 histopathological findings in the urinary system consistent with chronic obstructive nephropathy.

19 There was no effect of 2H4MBP exposure on the incidence of fetal skeletal abnormalities. Fetal  
20 findings were limited to an increase in the incidences of hydronephrosis of the kidney and  
21 enlarged liver in the 30,000 ppm group. A relatively high background incidence was found in  
22 this strain of rat for hydronephrosis (fetus incidence and range: 4/1,385 and 0.00%–0.81%),  
23 along with dilated renal pelvis (fetus incidence and range: 6/1,385 and 0.00%–1.06%), distended  
24 ureter (fetus incidence and range: 151/1,385 and 4.83%–15.36%), and hydroureter (fetus  
25 incidence and range: 11/1,385 and 0.17%–2.83%). Moreover, the background incidence of some  
26 findings (e.g., dilated renal pelvis and/or ureter) could be greater in fetuses than in pups,  
27 suggesting that these changes might be transient.<sup>18; 115; 116</sup> At necropsy of the F<sub>2</sub> offspring on  
28 PND 28, dilation of the renal pelvis was observed grossly in six rats in the 30,000 ppm group and  
29 in one F<sub>2</sub> rat in the control group. No incidences of hydronephrosis were observed in F<sub>2</sub> pups at  
30 necropsy; nevertheless, the observed fetal findings are consistent with the finding that the kidney  
31 and liver are target tissues for 2H4MBP-mediated toxicity.

32 In the current study, 2H4MBP exposure was associated with minimal apparent responses on litter  
33 size (fetal or PND 0) and fewer corpora lutea. A similar decrease in the numbers of corpora lutea  
34 and implants has also been observed at 30,000 ppm in the NCTR fertility and early embryonic  
35 development study, in which female dosing started two weeks prior to cohabitation through  
36 GD 6. No apparent responses were observed in the NCTR embryo-fetal toxicity study in which  
37 dosing is for a shorter duration (GD 6–15).<sup>93</sup> If 2H4MBP-related, this difference in response may  
38 be the result of the longer duration of exposure. The observed EE exposure-related decreases on  
39 PND 0 live F<sub>2</sub> litter size in the reproductive performance cohort, and GD 0 in the prenatal cohort  
40 (as well as total number of implants) is consistent with what has been observed in the 0.05 ppm  
41 EE group in the NCTR fertility and early embryonic development study.<sup>93</sup> These similarities  
42 demonstrate the consistency of responses observed with conducting a single study versus  
43 conducting three independent studies that would necessitate the use of more animals.

## 1 **Conclusions**

2 Under the conditions of this modified one-generation (MOG) study, there was *equivocal*  
3 *evidence of reproductive toxicity* of 2-hydroxy-4-methoxybenzophenone (2H4MBP) in  
4 Hsd:Sprague Dawley<sup>®</sup> SD<sup>®</sup> rats based on a decrease in F<sub>2</sub> litter size in both the prenatal and  
5 reproductive performance cohorts.

6 Under the conditions of this MOG study, there was *some evidence of developmental toxicity* of  
7 2H4MBP in Hsd:Sprague Dawley<sup>®</sup> SD<sup>®</sup> rats based on the observed postnatal growth retardation.  
8 The relationship of the increased occurrence of diaphragmatic and hepatodiaphragmatic hernias  
9 in F<sub>1</sub> adults and F<sub>2</sub> pups to 2H4MBP exposure is unclear.

10 Exposure to 2H4MBP was not associated with signals consistent with alterations in estrogenic,  
11 androgenic, or antiandrogenic action. Exposure to 2H4MBP was associated with lower F<sub>1</sub> and  
12 F<sub>2</sub> mean body weights; this effect on body weight contributed to the apparent 2H4MBP-related  
13 decreases in male reproductive organ weights. Mating and littering were not significantly  
14 affected by 2H4MBP exposure. Exposure to 2H4MBP was associated with nonneoplastic kidney  
15 lesions in the F<sub>0</sub>, F<sub>1</sub>, and F<sub>2</sub> generations. Expected estrogenic responses were observed in the EE  
16 group.

## 1 **A.1. Procurement and Characterization**

### 2 **A.1.1. 2-Hydroxy-4-methoxybenzophenone**

3 2-Hydroxy-4-methoxybenzophenone (2H4MBP) was obtained from Ivy Fine Chemicals (Cherry  
4 Hill, NJ) in a single lot (20100801), which was used for the dose range-finding and modified  
5 one-generation (MOG) studies. Identity, purity, and stability analyses were conducted by the  
6 analytical chemistry and study laboratory at Battelle (Columbus, OH). Reports on analysis  
7 performed in support of the 2H4MBP studies are on file at the National Institute of  
8 Environmental Health Sciences.

9 Lot 20100801 of the chemical was a light-yellow powder. The lot identity was confirmed using  
10 infrared (IR) spectroscopy and  $^1\text{H}$  and  $^{13}\text{C}$  nuclear magnetic resonance (NMR) spectroscopy. The  
11 IR spectrum (Figure A-1) was in good agreement with the anticipated structure and the reference  
12 spectrum (BP #824 from the Sadtler Basic Monomers and Polymers Library [Bio-Rad  
13 Laboratories, Hercules, CA]). Reference  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra for 2H4MBP were obtained  
14 from the National Institute of Advanced Industrial Science and Technology (NIAIST) (Tokyo,  
15 Japan) Spectral Database for Organic Compounds (SDBS No. 5800HSP-01-137 and 5800CDS-  
16 04-696, respectively). The Advanced Chemistry Development (ACD, Toronto, Canada) HNMR  
17 spectral prediction program (Version 12.01) was also used to predict these NMR spectra. Both  
18 the  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra obtained for lot 20100801 were consistent with these references.  
19 Additionally, a  $^1\text{H}$ - $^1\text{H}$  correlated spectroscopy (COSY) two-dimensional spectrum, Distortionless  
20 Enhancement by Polarization Transfer (DEPT)  $^{13}\text{C}$  spectral series, and  $^1\text{H}$ - $^{13}\text{C}$  heteronuclear  
21 multiple quantum coherence (HMQC) two-dimensional spectrum collected for lot 20100801  
22 were in good agreement with the anticipated spectra for 2H4MBP.

23 The purity of 2H4MBP lot 20080801 was determined using high-performance liquid  
24 chromatography (HPLC) with ultraviolet (UV) detection, as well as gas chromatography (GC)  
25 with flame ionization detection (FID). The HPLC/UV analysis showed a single impurity with a  
26 peak area <0.1%, indicating an 2H4MBP purity of approximately 100.0%. The chromatogram  
27 obtained from GC/FID consisted of a single major peak consistent with a purity of 100.0%.  
28 Lot 20080801 was screened for common residual volatile solvents using GC with electron  
29 capture detection (ECD) and FID; no significant volatile impurities were found. Differential  
30 scanning calorimetry (DSC) was also used to determine the purity of the test article. Analysis  
31 using a PerkinElmer (Shelton, CT) diamond DSC yielded a purity of 99.9% with a melting point  
32 of approximately 62°C. In addition, Karl Fisher titration of 2H4MBP lot 20080801 was  
33 conducted to estimate moisture content, which was found to be insignificant (<0.5%) in an  
34 analysis conducted by Galbraith Laboratories, Inc. (Knoxville, TN). Thus, the overall purity of  
35 2H4MBP lot 20100801 was determined to be >99.9%. Additional details on the chromatography  
36 systems used are provided in Table A-1.

37 Although the entirety of 2H4MBP came from lot 20100801, the chemical was received in eight  
38 drums (25 kg each) and not homogenized. Homogeneity analysis conducted on three samples  
39 taken during chemical handling using HPLC/UV found that the samples were statistically  
40 equivalent to the purity of the standard.

41 To ensure stability, the test chemical was stored in sealed amber glass bottles at room  
42 temperature (approximately 25°C). Periodic analysis of 2H4MBP lot 20100801 by the study

1 laboratory using HPLC/UV showed no degradation of the bulk 2H4MBP chemical prior to and  
2 during the animal studies relative to a frozen reference sample.

### 3 **A.1.2. Ethinyl Estradiol**

4 Ethinyl estradiol (EE) was obtained in a single lot (090M1241V) from Sigma-Aldrich (St. Louis,  
5 MO) via Government Scientific Source, Inc. (Reston, VA). Identity, purity, and stability analyses  
6 were conducted by the analytical chemistry laboratory at Battelle (Columbus, OH).

7 EE lot 090M1241V was a white powder. The lot identity was confirmed using IR spectroscopy  
8 and  $^1\text{H}$  and  $^{13}\text{C}$  spectroscopy. The IR spectrum (Figure A-2) was consistent with the available  
9 reference spectrum in the Sadtler Steroids, Androgens, Progestins, and Estrogens Library  
10 (Bio-Rad Laboratories, Hercules, CA). Reference  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra for EE were obtained  
11 from the NIAIST (Tokyo, Japan) Spectral Database for Organic Compounds. The ACD  
12 (Toronto, Canada) spectral prediction program (Version 12.01) was also used to predict these  
13 NMR spectra. Both the  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra obtained for lot 09M1241V were consistent  
14 with these references. Additionally, a  $^1\text{H}$ - $^1\text{H}$  COSY two-dimensional spectrum, DEPT  $^{13}\text{C}$   
15 spectral series, and  $^1\text{H}$ - $^{13}\text{C}$  HMQC two-dimensional spectrum collected for lot 09M1241V were  
16 in good agreement with the anticipated spectra for EE. Elemental analysis indicated that the  
17 sample was approximately 80.4% carbon, 11.5% oxygen, 7.9% hydrogen, and >0.5% nitrogen,  
18 which is consistent with theoretical values.

19 Purity assessment by HPLC/UV showed one impurity with a relative area of 0.23% of the total  
20 peak area, indicating an EE purity of 99.8% for lot 090M1241V. Analysis for volatiles using  
21 headspace GC/FID found that the sample contained approximately 0.023% acetone; no other  
22 volatiles were detected. DSC yielded a purity of 99.7% and a melting point of 184°C. Karl  
23 Fischer analysis indicated that the water content of lot 090M1241V was approximately 0.4%.  
24 These data indicate that the EE purity of lot 090M1241V was  $\geq 99.7\%$ , consistent with the  
25 manufacturer-reported purity of 99%. Additional details on the systems used are provided in  
26 Table A-1.

27 HPLC/UV analysis was used to determine the partition coefficient ( $\log P_{\text{ow}}$ ) for EE  
28 lot 090M1241V, and the average determined  $\log P_{\text{ow}}$  was 1.2, which is approximately one-third  
29 of the published  $\log P_{\text{ow}}$  value for EE of 3.7. However, calculation of the  $\log P_{\text{ow}}$  against  
30 additional comparison hormones produced a  $\log P_{\text{ow}}$  of 3.8, consistent with the published value.

31 To ensure stability, the EE positive control was stored in sealed glass containers at room  
32 temperature (approximately 25°C). Prior to the study and at study termination, lot 090M1241V  
33 was analyzed using HPLC/UV to ensure chemical stability.

## 34 **A.2. Preparation and Analysis of Dose Formulations**

### 35 **A.2.1. 2-Hydroxy-4-methoxybenzophenone**

36 Dosed feed formulations were prepared monthly (dose range-finding study) or eight times (MOG  
37 study) (Table A-2) using irradiated low-phytoestrogen feed (5K96 Casein diet). Formulations  
38 were stored at approximately 5°C for up to 42 days in amber glass bottles. Prior to beginning the  
39 study, the homogeneity of 1,000–50,000 ppm 2H4MBP formulations in 5K96 feed was  
40 confirmed using HPLC/UV. The analytical chemistry laboratory at Battelle (Columbus, OH)

1 conducted the homogeneity evaluation and all additional dose formulation analysis throughout  
2 the study.

3 Stability analysis was conducted on the 1,000 ppm formulation using HPLC/UV. When sealed  
4 and stored in amber plastic bags, the 2H4MBP formulations stored for 42 days at room  
5 temperature (approximately 25°C), refrigerated (approximately 5°C), or frozen (−20°C) were  
6 within 10% of the day 0 values. There was a slight declining trend in concentration (0.1%–0.2%  
7 per day) at all temperatures. To simulate conditions in the animal room, the 1,000 ppm  
8 formulation was stored in open glass containers with and without rodent urine and feces for  
9 7 days; no significant loss in 2H4MBP was found when analyzed with HPLC/UV relative to the  
10 day 0 values. The preadministration dose formulations were analyzed three times over the course  
11 of the study (Table A-3) using HPLC/UV. All preadministration samples were within 10% of the  
12 targeted dose; the largest variation was a 10,000 ppm formulation that was 5.3% above the  
13 targeted dose. For one set of dose formulations, postadministration samples were collected from  
14 the animal room approximately one month after preparation. These formulations were within  
15 10% of the target dose.

#### 16 **A.2.2. Ethinyl Estradiol**

17 Dosed feed formulations were prepared eight times (Table A-2) using 5K96 feed. Formulations  
18 were stored at −20°C for <57 days in sealed amber plastic bags. The homogeneity of 0.05 ppm  
19 EE formulations in 5K96 feed was confirmed before conducting the studies.

20 Stability analysis conducted on the 0.05 ppm formulation found that it was stable for 57 days  
21 when stored in sealed amber plastic bags at −20°C and usable for 57 days when store in sealed  
22 amber plastic bags at approximately 5°C and room temperature. An animal room simulation of  
23 the 0.05 ppm formulation in open glass containers without rodent urine and feces for 8 days  
24 showed formulations were within 10% of the day 0 value; however, when urine and feces were  
25 present, a slight decline in EE occurred.

26 The preadministration dosed feed formulations were analyzed three times over the course of the  
27 dose range-finding study (Table A-3) and four times over the course of the MOG study  
28 (Table A-4) using HPLC/UV. All preadministration samples were within 10% of the target  
29 concentration with the exception of two formulations, one of which was that were 11% below  
30 and the other 12% above. Postadministration samples were collected from the animal room at the  
31 end of the exposure period and sent to Battelle (Columbus, OH) for analysis. The concentration  
32 of the animal room sample was within 10% of the preadministration analyses and, therefore,  
33 demonstrated acceptable stability during its use in the study.

1 **Table A-1. Chromatography Systems Used in the Modified One-Generation Study of**  
 2 **2-Hydroxy-4-methoxybenzophenone**

Chromatography	Detection System	Column	Mobile Phase
<b>System A</b>			
HPLC	UV (289 nm)	Phenomenex, Synergi Fusion RP; 100 × 4.6 mm, 4 μm	40/60 acetonitrile:ASTM Type I water; flow rate 1.2 mL/min
<b>System B</b>			
HPLC	UV (289 nm)	Phenomenex, Synergi Fusion RP; 100 × 3 mm, 2.5 μm	40/60 acetonitrile:ASTM Type I water; flow rate 0.8 mL/min
<b>System C</b>			
HPLC	UV (289 nm)	Phenomenex, Synergi Fusion RP; 100 × 3 mm, 2.5 μm	40/60 acetonitrile:ASTM Type I water; flow rate 0.8 mL/min
<b>System D</b>			
GC	FID	Restek, Rtx-5; 30 m × 0.32 mm, 1.0 μm film thickness	Helium; flow rate of ~3 mL/min
<b>System E</b>			
GC	FID; ECD	Restek, Rtx-624; 30 m × 0.53 mm, 3 μm film thickness	Helium; flow rate of ~5 mL/min
<b>System F</b>			
HPLC	UV (280 nm)	Phenomenex, Luna; 250 mm × 4.6 mm, 5 μm film thickness	50/50 acetonitrile:ASTM Type I water; flow rate 1.0 μL/min
<b>System G</b>			
HPLC	UV (205 nm)	Thermo, BDS Hypersil; 100 mm × 4.6 mm, 3 μm film thickness	65/35 acetonitrile:ASTM Type I water; flow rate 1 mL/min

3 HPLC = high-performance liquid chromatography; UV = ultraviolet; ASTM = American Society for Testing and Materials;  
 4 GC = gas chromatography; FID = flame ionization detection; ECD = electron capture detection.

5 **Table A-2. Preparation and Storage of Dose Formulations in the Modified One-Generation Study**  
 6 **of 2-Hydroxy-4-methoxybenzophenone**

Preparation
Stock solutions of 2H4MBP or EE were prepared by weighing the appropriate amount of lot 20100801 (2H4MBP) or lot 090M1241V (EE) into volumetric flasks and bringing to volume with methanol. Flasks were sealed and mixed well to ensure the test articles thoroughly dissolved. Irradiated 5K96 feed was weighed into amber glass bottles to which stock solution and methanol were added to create the proper 2H4MBP or EE concentration. Bottles were sealed and rotated end-over-end for 30 minutes to ensure homogeneity. Over the course of the study, eight dose formulations were prepared.
<b>Chemical Lot Number</b>
20100801 (2H4MBP) 090M1241V (EE)
<b>Maximum Storage Time</b>
42 days (2H4MBP) 57 days (EE)

## 1 C.1. Methods

2 Rodents used in the National Toxicology Program are produced in optimally clean facilities to  
 3 eliminate potential pathogens that might affect study results. The Sentinel Animal Program is  
 4 part of the periodic monitoring of animal health that occurs during the toxicological evaluation of  
 5 test compounds. Under this program, the disease state of the rodents is monitored via sera or  
 6 feces from extra (sentinel) or exposed animals in the study rooms. The sentinel animals and the  
 7 study animals are subject to identical environmental conditions. Furthermore, the sentinel  
 8 animals come from the same production source and weanling groups as the animals used for the  
 9 studies of test compounds.

10 For this modified one-generation study, blood samples were collected from each sentinel animal  
 11 and allowed to clot, and the serum was separated. All samples were processed appropriately with  
 12 serology testing performed by IDEXX BioAnalytics (formerly Rodent Animal Diagnostic  
 13 Laboratory [RADIL], University of Missouri), Columbia, MO, for determination of the presence  
 14 of pathogens.

15 The laboratory methods and agents for which testing was performed are tabulated below; the  
 16 times at which samples were collected during the studies are also listed (Table C-1).
